HOW A LAWYER THINKS *

LORD RADCLIFFE
P C, G B E, M A Oxfd
A LORD OF APPEAL IN ORDINARY

MANY people are becoming more and more vexed by e problem of communication There seems some son, to think that, as our technical mastery of the ans of communication increases, there is a correponding decrease in our power to employ those means in y way that is worthy of their possibilities Whether his is more than a coincidence I do not know What is any rate worthy of remark is that we still appear to nderstand each other so little

If we lived in a less complicated less interdependent rm of society, the want of understanding might be of particular importance Earlier societies have got on, ten happily enough, with a minimum of common nderstanding between their different classes and ections Retrospect may to some extent flatter English ciety of an earlier age, but it was probably rather ceptionally fortunate in the range of common feeling at united it, despite huge barriers or gaps It would not ave been altogether nonsense to talk of a common ulture informing that earlier society less misleading han it might be to talk of it today Most of what now ok like the prevailing causes—a general and dominant ligious faith, a still unbroken association with the land, e influence of insularity, the sheer effect of a simple cial organism—have ceased to operate, even though me of the institutions that were founded upon them ay still survive And at a period when our complex lationships make it essential that we should understand ch other or perish, we understand each other, perhaps, ss and less

If you do not have common ideas, you cannot have a mmon speech That is, if the words that a speaker es either do not mean the same thing to his listener they mean to him, or, more simply, do not mean anything to the listener at all, there is either misunderstanding or no understanding In either event there is o communication in any valuable sense of the word t is hard enough for the specialist to realise this , but at ast he is conscious of some necessity for a free translation, if he is to make himself generally understood ut the realisation is harder yet, I believe, for the man f general literary education—the man, let us say, whose ducation was directed towards or culminated in the arts egree at a university. For the conceptions which were planted in him by that form of education, itself erived from the common culture of the older Europe, ssume a certain fixed relationship between words and eas, and assume moreover that, because of that lationship, words, properly combined, are an adequate ehicle for the expression of ideas Deny him the alidity of that assumption and he becomes something a lost man in the modern world That sovereign strument for communicating ideas, which he thought bridge between his own and other minds, becomes only ne more of those esoteric jargons in which specialists ell the sign language of their tribe Puffs of smoke on he hill, knife markings on a tree, rock carvings of a rgotten pictogram And, since many of the leading en in our public and professional life have been raised s the products of a literary general education of this nd, and there are even some who think it a good thing hat they should have been, it is no wonder that the roblem of communicating meaning, or, to put it another ay, the problem of expounding ideas, is today thought of as a serious one For these men may understand each other, if they listen, but it is very doubtful whether they possess the ability to make themselves at all generally understood

Essentially the problem is not one that turns upon a relationship between leader and led or between those who prophesy and those who are prophesied to We live, of course, in a managerial age, and management—political social, or industrial—is very largely the art of communicating ideas in a persuasive form But everyone has always lived in a managerial age of some kind It distorts the problem to think of communication in terms of "putting things over," an amiable method of getting one's own way So understood, the art of communication appears as little more than one of the techniques of public relations It seems to me much more fruitful to approach the problem as a search for a modern art of generating ideas by a free exchange of them We ought to try to gather together at any rate the cultured classes—pass the phrase for the moment without assuming that it is necessarily priggish—from the isolation which the specialisation of learning is tending to bring about Because this isolation is a harmful thing and it is something of a new phenomenon in European life It is a very natural product of two things which press upon us all today—the lack of any agreed curriculum of general education, and the great additions to specialised knowledge in so many fields, which give so few of us enough time to put our noses outside our own books It is natural enough, under prevailing conditions but more and more its effect will be that even the professional classes will understand each other's concepts and language less and less, and the common ground of enlightened opinion on which so many people have stood firmly in the past will shrink to a negligible plot So let us be upon our guard against this new threat of Enclosures !

* * *

This is rather too grave an introduction for the simple reflections that are to follow But my own professional training has been in the discipline of the Law , and when the Royal Society of Medicine did me the honour of inviting me to deliver the Lloyd Roberts lecture, adding considerately, "the subject is not necessarily medical," I thought to myself that it is sometimes more interesting to know how a thing works than what it does How does a lawyer work ? It might make some contribution to the mutual understanding between Medicine and Law if I were to reflect a little upon the main influences that govern a lawyer's way of thought Any worthwhile profession sets its mark upon a man just as surely as the ancient callings did—sets its mark upon his mouth and his hands and his eyes, and speaks a little through his voice But apart from the physical uniform, it imposes too, certain patterns of ideas or modes of thought, and unless these are fairly understood the language which is their vehicle of expression remains a foreign language People used to speak of the three learned professions, the Church, Medicine, and the Law. Now university research has so much extended that Learning itself has become a profession . But how far do we understand each other today, where we hope to go, and where we would like to stand ?

* * *

I believe that one of the noteworthy things about the lawyer in our present age is that the system of knowledge which constitutes his learned study is not itself a progressive one Progressive, of course, is an equivocal term But the world today is humming with the murmur of those who study and apply the expanding sciences and who see before them an unconfined field of experiment and discovery Physics, Chemistry, Biology I suppose that there can be few people who feel themselves to have reached some mastery of those subjects who do not feel at the same time that the work of the past was only a preliminary to the almost unpredictable developments of the future. Now to live and work in a world of that kind, which by the very terms of its existence is a revolutionary world, must be intensely exciting. And the excitement of those who understand what is going on communicates itself to the general public. You may have guessed already what I am going to hint at, that it does not communicate itself to me. I wish that it did. It is a depressing experience to attend some great ceremonial procession with the crowd waving and cheering madly and to feel cut off from the whole thing, neither able to see the procession nor to share the excitement. It is obvious, indeed, that the great advances in what for want of a better word I will call the scientific sciences are going to modify, even to revolutionise, the conditions under which human life has to be lived. But it is not equally obvious that the alteration of those conditions will alter in any important way the terms of the human dilemma itself. No doubt an expedition will reach the Moon in due course, or some inhabited constituent of the solar system, but suppose none of the inhabitants has ever got further than writing the *Iliad* or *Hamlet* or *King Lear* or *Don Quixote*?

---

* The Royal Society of Medicine's Lloyd Roberts lecture for 1955, delivered on Nov 30, and published with the society's permission

I speak as if the lawyer were the contemplative philosopher of the present day. He is not at all, at any rate in this country. Law is not a reflective calling it can hardly afford to be, since its essential function lies in the discovery and application of practical rules which have to be treated for the sake of appearances as if they were universals. But all the same there is something rather unusual, something which might be characterised as introverted, about a profession in which the range of learning is, in effect, closed and in which a principle is the more treated as valid the more it can be shown to be ancient and long-established. Such a background should favour a certain conservatism and a certain detachment of outlook. It should favour, too, an almost desperate humanism as the best justification of our, perhaps, dying art. On the whole I think that this is what our background does. But since the lawyer revolutionary is himself a recurrent figure in the historical process, I take it that there is something in the legal discipline which produces by reaction the extreme antithesis of the normal type.

* * *

You cannot be a good lawyer unless you can cultivate good historical sense. The more you try to understand the reason or principle that lies behind any branch of our jurisprudence, the more you are forced to see that it is not Reason in itself but a decent rationalisation of attitudes, moral or social, which belong to the history of our society. When I was a young man I used to get rather embarrassed by this. I used to think that it rather lowered the status of Law and of our learning in it. Now I do not feel quite the same way. It seems to me that the life of man in society is so complex a thing that good social habit which has some root in the past, which is nourished by the emotional association of history, is a more valuable possession for the individual than a mastery of a dialectic which may be intellectually more satisfying. Not all of us in fact know much about history and very few of us know as much as we should but nevertheless I think it true as a generalisation that to the lawyer the history and the historical development of his country convey a more vivid sense of living and practical reality than they do to others who follow other callings. We are so often forced to see the present in its true light as a point of time in a continuous process which does not itself pause for time. That is a strength at least it should give a certain richness at the expense of a certain soberness, of tone.

* * *

Most people think of the lawyer as a great arguer. Argument is, I suppose, the most typical weapon of the lawyer's armoury. How much it governs his real thinking seems to me worthy of some analysis, since it may help to show how ambiguous a word "argument" is. On the one hand, undoubtedly, the administration of law consists in the application of principles to particular combinations of circumstances. The combinations are regarded as new, the principles as given or at any rate as demonstrable by deductive reasoning based upon other principles. Deductive logic therefore plays a large part in the legal process, being employed alike by the advocate to present his argument and by the judge to support his decision. The decision as arrived at is arrived at, accordingly, as a demonstrated necessity and this use of the logical process, which those trained in it have been taught to regard as infallible, satisfies the general conception of what we need of justice, that it should be certain, impartial, and, above all, impersonal. We can say of the lawyer, then, that he is a person who is conditioned by his training to marshal the expression of his thoughts in the form of logical reasoning.

Away from the Law Courts, this habit does not tend to make the lawyer a good controversialist. His method smacks too much of scholastic debate in the Middle Ages, in which it was essential to success that one contestant should never allow the other to get away for one moment with a single uncertain premise. If he did, there was no breaking the chain of unchallengeable deductions that would soon be tied to it. So he cried *At distinguo*, and pulled the other back to the beginning. It was a good discipline for those who can attribute to words precise and definite meanings. But public controversy needs an altogether looser rein. It requires the impressionist technique. What is important is not so much where the other man gets to what matters more is the significant effect produced by the whole arrangement. And to achieve the effect a few striking passages may be much more compelling than the logical consistency of the whole.

But the interesting thing is that, though all lawyers instinctively resort to deductive reason to demonstrate their conclusions, it is in practice by no means the strongest part of their equipment. A professor of logic would find in even famous judgments some sad howlers—the undistributed middle, transference of meaning in the use of the same word, questions begged until they are in rags. And not only the professor of logic. Ask an intelligent member of the public to make a critical study of some well-known judgment and to give his comments. He would find much to admire—a good, if rather desiccated, style of prose, clarity of exposition, economy of expression and a reassuring air of detachment but what I do not believe that he would be impressed or convinced by is the reasoning itself. I do not say that he would fault it as the professor might, but I think that his readiness to be satisfied with the result of a trial would arise more from his satisfaction with the judge himself, the conduct of the proceedings, and the treatment of the witnesses, than from any feeling that the considerations which were ultimately held to be the determining ones were based upon the kind of reasoning that he would himself be convinced by in the critical decisions of his own life. In particular, the distinctions upon which the result seems to turn often present themselves as somewhat unreal, not so much as points of substance as fine points of verbal distinction.

Now most lawyers would find an answer to this kind of criticism, although they are not very ready to offer it. If it was offered more often and more explicitly it would help to a better general understanding of what is the true structure of legal reasoning and might mitigate the impression, quite widespread, that law must seem much more convincing to lawyers than it does to the outside world The thing to be admitted is that Law is not in any sense an exact science, indeed it is not in the modern sense of the word a science at all Its material consists of the conduct and the affairs of living human beings in all the complexity of their relations, and its art consists in the application of certain generalisations styled principles, to a particular combination of circumstances These generalisations are themselves half moral half practical in each case the compound is produced more by perception than by rule It is a mistake to suppose that logic based on verbal propositions can ever be much of a guide for this purpose, and I have the impression that lawyers more or less unconsciously accept that their formal process is not their real one The real process the mastery of which constitutes the abiding fascination of administering law, proceeds by the method of selection and arrangement Once the picture has been composed by the artist there is indeed something inevitable in the resulting impression but, of course, the art has lain in the justness of the selection and the firm outline of the pattern

* * *

Perhaps you will allow me to illustrate what I am saying by an extract taken from a well known judgment in the House of Lords by one of the greatest exponents of the legal art that this country has known The speaker is Lord Macnaghten , the period 1888 the setting a late-Victorian, foggy, lamplit Christmas Eve at Paddington , the subject a Gladstone bag lost at the station by a certain Mrs Bunch Mrs Bunch is now at grapples with the Great Western Railway as to which of them is to bear the burden of the loss This is how Lord Macnaghten deals with the problem

"Your Lordships are familiar with the evidence in this case, and I do not propose to repeat it It is enough to say that on the 24th of December 1884 at 4 20 p m Mrs Bunch came to Paddington with a Gladstone bag and some other luggage, meaning to travel with her husband by the 5 p m train to Bath, that on her arrival at the station her luggage was received by a porter in the employment of the company, and taken by him to the platform for the purpose of the journey, and that the Gladstone bag was last seen on the platform with the same porter a few minutes afterwards From that time all trace of the bag is lost The porter and the bag both vanish from the scene It was suggested by the learned counsel for the appellants, by way of explanation, that the porter was possibly one of a number of men picked up by the company for the day to meet the pressure of Christmas traffic But I may observe, in passing, that so far as the public was concerned, there was apparently nothing to distinguish the casual helper of whom little if anything, was known, from the regular and trusted servants of the company

"On these bare facts standing alone it seems to me that there would be evidence upon which the County Court judge might reasonably find for the plaintiff even if the company were not under the liability of common carriers as regard the lost bag

"But then it was contended with much earnestness that it ought to have been inferred from the circumstances of the case and from Mrs Bunch's conduct that at the time of the loss the bag was not in the custody of the company for the purpose of the journey It was said that Mrs Bunch *came to the station too soon—that* she came before the train was drawn up—that she broke the journey, if the journey is to be taken as having begun—and left the bag in the charge of a porter who was then not acting as the servant of the company within the scope of his authority as such, but acting as her agent in his individual capacity, and that if this was not what she meant, it was an attempt on her part to saddle the company with a liability which they were not bound to undertake

"It seems to me that there is no substance in any of these objections Mrs Bunch, no doubt, came to the station somewhat early But the one thing that railway companies try to impress on the public is to come in good time And considering the crowd likely to be attracted by cheap fares during the Christmas holidays, and the special bustle and throng on Christmas Eve it does not seem to me that Mrs Bunch came so unreasonably early as to relieve the company who received the luggage from the ordinary obligations flowing from that receipt It is impossible to define within the extreme limits on both sides the proper time for arrival Everything must depend upon the circumstances of the particular case But, among those circumstances, the least important, as it seems to me is the time when the train is drawn up at the departure platform That is as everybody knows, a very variable time And it is a matter over which the passenger has no control, and of which he can have no notice before he comes to the station

"Then I think that there is nothing in the conversation which took place between Mrs Bunch and the porter Mrs Bunch s question was a very natural one The answer which she received was just what might have been expected Nine women out of ten parting with a travelling bag on which they set any store would have asked the same question In ninety-nine times out of a hundred the same answer would be returned I do not think that this conversation altered the relation between the parties in the least degree It seems to me almost absurd to treat it as a solemn negotiation by which the lady abdicated such rights as she possessed against the Great Western Railway Company and constituted this ephemeral and evanescent porter in his individual *capacity the sole custodian of her Gladstone bag*

"Nor can it, I think, be said that Mrs Bunch broke the journey by leaving the platform to meet her husband and get her ticket To take a ticket is a necessary incident of a railway journey It is at least, a very common incident in railway travelling for persons, who intend to travel in company, whether they be members of the same family or not, to meet by appointment in the railway station from which they mean to start, and it is certainly not unusual in such a case for the purchase of tickets to be deferred until the meeting takes place . "

"It was said that if everybody acted as Mrs Bunch acted in this case, railway companies would require an army of porters, and that it would be almost impossible for them to carry on their business I quite agree, but I am not much impressed by that observation I apprehend that if all travellers acted precisely alike, if everybody arrived at a station for a particular journey at precisely the same moment, though the time of arrival were the fittest that could be imagined, there would be no little confusion, and perhaps some consternation among the railway officials Whatever may be the result of your Lordship's judgment, there is no fear that it will have the effect of making everybody act alike Things will go on just as usual The fidgety and the nervous will still come too soon , the unready and the unpunctual will still put off their chance of arrival till the last moment, and the prudent may have their calculations upset by the many accidents and hindrances that may be met with on the way to the station And it is just because of the irregularity of individuals that the stream of traffic is regular and easily managed "

Now there are several things that might be said by way of commentary on this specimen of judicial reasoning I would like to draw your attention to one or two of them First, though this may seem merely an incidental comment, the style is very nicely fitted to the subject It is grave, without being portentous it is admirably detailed, without being finicky , and at the same time there is, I think, at the back of it a gleam of decorous amusement that these sober legal propositions have to be marshalled and weighed to solve the problem of Mrs Bunch and her Gladstone bag Next, these paragraphs which seem to be no more than a recital of facts or a rather quizzical glance at certain arguments, do in fact contain an exposition of legal principles—so much so that Mrs Bunch's case has become a leading case determining for good the kind of considerations that are to govern the loss of Gladstone and other bags at railway stations and the weight to be given to some of those considerations But the legal principles are, as it were, built into the factual structure of the story itself not imposed upon it, so that the story seems to arrange itself naturally round them and to take its form and order from their intrinsic logic (This quality of design is a quality common to all great artists, in whatever medium they work They speak as one having authority, not as one bound by other men's measure They do not labour at odds with their material A master of his art is a master of his means and under his hands formless mass glows to clear outline and coherent shape) And, lastly, the whole passage, though the careful simplicity of it is to some extent delusive, is irradiated by a vivid common sense, the most difficult of all qualities for the lawyer to incorporate into his work

I do not mean to level that as a cheap generalisation It is quite true that in every calling which is primarily intellectual it is easy to reason oneself away from common sense The Law is not singular in that respect, though its immediate application to the practical affairs of living throws its defects into the sharper relief But common sense is not itself the highest of human qualities nor is it the final arbiter in our affairs The lawyer's problem is not understood unless it is understood as a problem, never completely resolved, of keeping his conclusions sufficiently related to common sense without subordinating them to it Perhaps I could describe his process as away from common sense by way of reason and then back to common sense to test the conclusion And his difficulty is enlarged by the fact that the Law, for all its portentousness, for all that it must affect to deal with the issues of life and death, of honour and dishonour, of fortune and ruin, is condemned to make its survey over a limited field which covers always much less than the whole subject *This* consideration is admissible, *that* is excluded For *this* purpose the Court may learn of a man's motive, for *that* purpose it is to be treated as irrelevant The human heart may be the prime mover in most of the combinations of events that come before a court of law's review, but only a very limited acknowledgment can be permitted either of its existence or of its impulses There would be little worth honouring in the Law if it could not relate its judgments to a sense of morals, and yet we know that a court of law is not, and is not free to be, a court of ethics in itself

I do not criticise the ambiguity of attitude that is forced upon us by these limitations Nor, I think, do most lawyers No one could practise law without realising that some such limitation is unavoidable It is not the purpose of this lecture to rehearse the reasons Every case has to be seen as one step only in the process of administering justice, and administration creates its own necessities—of time, of good order, of what is in the true sense triable and what is not Law is essentially a generalisation—how can it provide even handed justice if it is not ?—and the rules and principles which we apply are the product of those generalisations So, although we must dispute as to the application of the rules and as to the qualifications upon them that ought to be recognised, I think that we are conditioned to acceptance of the idea that in the Law we practise an imperfect art, and that the judgments which we pass, however profoundly meditated, are valid only within the terms which we ourselves impose upon the insoluble complexity of life

* * *

It is not easy to explain this attitude to the lay world, since it is the lawyer's mystery

Ostensibly, the Law is portentous in its claims But I do not think that any lawyer who is either sensitive or sensible feels that he is portentous in himself, despite the terms of expression which his subject almost forces upon him Among the several forms of legal humour, much of it esoteric, you can sometimes notice a rather grim anger at the ambiguity of a position in which by the very condition of his calling the lawyer is prohibited from speaking, though he cannot be prevented from feeling Often such expressions pass for a merely macabre or even ghoulish brand of humour, of a kind that professions do indeed generate Sometimes they are , but so to write them off is, I think, to miss a quality of feeling that has always seemed to me an important part of the make up of a lawyer Let me try to make good an instance or two of this kind of irony

There is a record of an 18th century judge on assize at Stafford, who sentenced a man to death, as law then required, for uttering a forged bank note He charged him to prepare himself to leave this world for another where, said the judge, it was to be hoped that "through the merits and mediation of our blessed Redeemer he would experience that mercy which a due regard for the credit of the paper currency of this nation forbade him to hope for here " Of course, you may take that in more ways than one the bland 18th century philosophy of the Powers that-Be , a small, macabre, private joke , or, as I think, a sudden, Swiftian flash at man's unending inhumanity to man

Max Beerbohm attended Sir Charles Russell's famous cross examination of the forger Pigott during the sitting of the Parnell Commission There were the three Lords Justice, as aweful as only Victorian judges, perhaps, could be there was the pitiable Pigott, who was to kill himself a few days later, mumbling and stumbling in his exposure and there was Sir Charles Russell, the most overwhelming man of his period, addressing him " Come, Mr Pigott, strive to do yourself justice Remember you are face to face with my Lords ! " Portentousness ? mumbo-jumbo ?—or one brief commentary on the whole judicial scene ?

Few lawyers can be quite easy in the reflection that the rights of a litigant who can afford to spend money on the presentation of his case are more readily safe guarded than the rights of one who cannot " The gates of the Courts of Justice are open to rich and poor alike ", one judge has said, " so are the doors of the Ritz Hotel " The comment in different dress is much older than the Ritz but I doubt if it will ever be repeated just as a joke

On one occasion, which has now passed into history, a few sentences on the same theme are said to have done much to bring about a major change in the law of the country Up to the middle of the last century there were no divorce courts marriage could be dissolved at law by one process only, the obtaining of a special Act of Parliament Few people had time, influence, or money enough to resort to this other persons whose marriages went astray and who desired a second union had the choice between the crime of bigamy and the scandal of open adultery In 1845 a labourer was prosecuted at Warwick Assizes on a charge of bigamy to which he pleaded guilty The judge, Mr Justice Maule, sentenced him in these words

"Prisoner at the bar, you have been convicted of the offence of bigamy, that is to say, of marrying a woman while you had a wife still alive—though it is true that she has deserted you and is living in adultery with another man You have therefore committed a crime against the laws of your country, and you have also acted under a very serious misapprehension of the course which you ought to have pursued You should have gone to the ecclesiastical court and there obtained against your wife a divorce *a mensa et thoro* You should then have brought an action in the courts of common law and recovered, as no doubt you would have recovered, damages against your wife's paramour Armed with these decrees you should have approached the legislature and obtained an Act of Parliament which would have rendered you free and legally competent to marry the person whom you have taken on yourself to marry with no such sanction It is quite true that these proceedings would have cost you many hundreds of pounds, whereas you probably have not as many pence But the Law knows no distinction between rich and poor The sentence of the Court upon you, therefore, is that you be imprisoned for one day, which period has already been exceeded, as you have been in custody since the commencement of the assizes."

The prisoner was released. Only a few years later the requirement of an Act of Parliament to dissolve marriage was abolished and our modern divorce court was set up under which divorce is obtained by judicial process.

* * *

I have the feeling that the lawyer's processes of thought, as I have presented them to you, are such as to make him rather a figure on the side-lines of the game as it is played today. But then Law itself, his native art, is coming to stand rather on the side lines of modern civilisation. His status is still a high one, but this eminence he owes in part to the very great value that was placed upon his calling in the earlier forms of our own society. He enjoys therefore an inherited prestige which is out of proportion to the current evaluation of the services which Law can render. The reason, I believe, lies in that change of attitude which is at once the cause and the consequence of the present age. There is not really much to be said for Law unless it is thought of as representing absolute standards of right and wrong, even at a far remove. But then that means that its fundamental rules, whatever they are, stand above and independent of social needs and aspirations of the day. The function of the lawyer, you might say, is to reconcile the demands of human nature to the acceptance of those rules. There are periods of historical development when men prize very highly such a service of reconciliation. I do not think that this is one of those periods. The vast possibilities of material change and advance have made men haughty to their institutions. Their institutions must serve them, absolutely, and they will not in any way serve their *institutions*. So be it: but a lawyer remains, first and last, an institutionalist, and the lawyer, his equipment a little rusty, his habit a little worn, not quite the tremendous figure of the past, stands compactly on one side, content to wait his turn.

DIETETIC TREATMENT OF PEPTIC ULCER

R. DOLL

RADIOLOGIST, CENTRAL MIDDLESEX HOSPITAL

FOR over a century the principal treatment of peptic ulcer has consisted in the restriction of the diet to "bland" foods. At one time a preliminary period of starvation was recommended (Leube 1876, Riegel 1903), but it has been more usual to start treatment with a diet of milk, eggs, and perhaps cream, and subsequently to add other soft and "non-irritating" foods (Lenhartz 1904, Sippy 1915, Hurst and Stewart 1929). Under the influence of Meulengracht (1934) the use of very limited diets has largely been abandoned, but most patients are still provided with a long list of foodstuffs which they are advised to avoid.

The value of a special diet has never been demonstrated by a controlled series of observations, and it must be presumed that its use is continued partly for reasons of tradition, partly on the theoretical grounds (ill supported in practice) that "bland" foods stimulate less secretion than other foods and do not "irritate" the ulcer physically, and partly because patients given a restricted diet tend to lose their pain. It is, however, now realised that the bouts of pain associated with the presence of an ulcer are nearly always self-limiting, and it is widely held that the duration of the bouts can be influenced by psychological means. Several workers have, therefore, questioned whether dieting has any specific effect. Nicol (1942) and Lawrence (1952) compared the results obtained by giving patients a full diet with those obtained by a standard ulcer regime, and neither found that the standard régime had any advantage.

The present investigation was planned to be a controlled trial of certain types of special dieting. In the first part of the investigation a comparison was made between the rate of healing of gastric ulcers in patients treated in hospital by two different diets; in the second, the frequency with which symptoms recurred and the ulcer remained unhealed was compared in two series of outpatients with gastric or duodenal ulcers who were recommended to adhere to different dietetic schedules.

Inpatients with Gastric Ulcers

The inpatient trial was part of a long-term investigation into factors affecting the rate of healing of gastric ulcers. The type of patients admitted for treatment and the general plan of the investigation have been described in detail elsewhere (Doll and Pygott 1952, 1954, Doll et al. 1956).

In order to obtain more information in a limited period, the effects of three different types of treatment have been assessed concurrently. The different treatments have been allocated to patients in such a way that the group of patients who have been given a specific treatment and the group not given it have each contained the same proportion of patients given each of the other treatments; hence, the value of each treatment can be assessed independently. In the present trial the contrasted methods of treatment were: (1) a standard ulcer diet, and an almost normal ward diet; (2) continuous intragastric milk drip, and no drip; and (3) advice to smokers to stop smoking, and allowing them to continue smoking.

With milk drip pain appeared to be relieved somewhat more quickly than without it, but no effect could be detected on the rate of healing of the ulcers (Doll et al. 1956). Insufficient patients have yet been advised to stop smoking for assessment of the value of this advice; no interaction has been observed between the advice and either of the two diets, and it is thought that any effect which may be attributable to it can be ignored in assessing the value of the diets.

TABLE I—COMPARABILITY OF PATIENTS ON ADMISSION WITH REGARD TO PRESENCE OF PAIN, BODY WEIGHT, AND SIZE OF ULCER

Characteristics	No. of patients on	
	Standard ulcer diet	Almost normal diet
Pain on admission		
Present	21	24
Absent	11	8
Initial weight		
Under 7 st.	2	3
7 st. –	8	7
8 st. –	8	7
9 st. –	2	4
10 st. –	8	3
11 st. +	4	5
Not recorded	0	3
Av. all patients (st., lb., oz.)	9, 0, 7	8, 13, 12
Initial size of ulcer niche (sq. mm.)		
10–24	9	8
25–49	9	7
50–99	7	7
100 +	7	10

TABLE VIII—RELIEF OF SYMPTOMS DURING INPATIENT TREATMENT FOR GASTRIC ULCER REPORTED IN VARIOUS STUDIES

No of patients	Treatment	Proportion pain free (%)	Proportion with occasional pain or dyspepsia (%)	Proportion with daily pain for 1 wk or longer (%)
16	Almost normal diet*	19	56	25
16	Standard bland diet (present investigation)*	44	38	19
40	Standard bland diet (Doll et al 1956)*	38	40	23
31	Standard bland diet (Doll and Pygott 1952)†	42	29	29

* Excluding patients treated with milk drip

† Excluding 1 patient with an ulcer niche initially less than 10 sq mm in profile

One other controlled trial of dietetic treatment has been reported

Lawrence (1952) treated 140 inpatients with gastric, duodenal, or jejunal ulcers by a modified Lenharz régime or by a "full convalescent" diet including "fried foods, cheese and pork pies" and without sieving or special preparation of vegetables or fruit Alternate patients received one régime, the remainder the other All patients were given the same drugs and (with certain exceptions equally distributed in the two treatment groups) were kept in bed until the ulcer was radiographically healed Healing of the ulcer was obtained in 93% of patients on both treatments, in average times of 58 days for those on the full diet and 64 days for those on the Lenharz diet Pain was abolished in 94% of patients on both treatments, in average times of 25 and 26 days respectively Lawrence noted that some patients on the full diet "were at first dubious of a régime so much at variance with their earlier instructions but their anxiety was allayed when it was explained to them that such food was required to inactivate their over potent gastric juice"

These results should not be interpreted as signifying that the pathogenesis of peptic ulcer is entirely unrelated to diet But specifically harmful or curative factors—if they exist—do not appear to have yet been adequately identified So far as the healing of ulcers is concerned, it may be concluded that there is no advantage to be gained from limiting the diet to "bland" foods—that is, not in the way that diet is commonly limited in hospital Even fried foods, which were excluded from both types of diet given to inpatients in the present investigation, were not harmful in Lawrence's study, and no harm could be demonstrated from allowing their use to outpatients in the present study

In both investigations inpatients on the standard ulcer diets had 2-hourly feeds, and patients on the more normal diets had snacks on waking, at mid-morning, and at bedtime While, therefore, patients on the more normal diets had two less feeds a day than the patients on the ulcer diets, they did not have as long intervals between food as many people have It may be concluded that strict 2 hourly feeds have no greater beneficial effect on the rate of healing of gastric ulcers than feeds at the longer intervals adopted for the control diets, but no evidence has been obtained about the value of snacks between meals

Whether "bland" foods and 2-hourly feeds were of value for the relief of pain is uncertain The small difference observed in part of the present investigation might have disappeared if a stronger attempt had been made to convince the patients that the unaccustomed diet was harmless

Summary

The value of the dietetic treatment of peptic ulcer by means of "bland" foods has been assessed on (1) 64 inpatients with gastric ulcers, and on (2) 80 outpatients with gastric ulcers and 50 outpatients with duodenal ulcers

The inpatients were divided into two equal groups, patients in one group were given the standard hospital ulcer diet, while in the other they were given an almost normal diet The diets were strictly supervised throughout

The results showed a slight but statistically insignificant advantage to the patients on the "almost normal" diet with regard to the proportion in whom the ulcers became completely healed (10/32, compared with 5/32) and the average amount healed for the whole group (70 3%, compared with 65 1%), and (if patients on milk drip are omitted) a significant advantage in the average amount of weight gained (5 lb 8 oz, compared with 2 lb 14 oz), on the other hand, they showed an appreciable advantage to the patients on the standard ulcer diet with regard to the proportion who reported themselves completely free of pain throughout treatment (17/32, compared with 9/32)

The outpatients were either advised to continue for a year on the standard ulcer diet with which they had previously been treated, or were advised to revert to a wholly normal diet At the end of a year the proportion who had remained free of pain and in whom the ulcer was radiographically healed was practically the same in the two groups (pain free 22% and 21%, ulcer healed 45% and 51%)

Dieting with "bland" foods does not increase the rate of healing of peptic ulcers

We are grateful to Dr F Avery Jones and Dr T D Kellock for referring patients to us for treatment, and to the dietitians and other members of the staff of the gastro enterological and radiological departments of the hospital for their assistance in the care and investigation of the patients

Appendix

Inpatients on the standard ulcer régime were given the basic diet for the first 2 weeks of treatment and the convalescent diet for the subsequent two weeks

Basic diet Two hourly feeds from 6 A M to 10 P M

6 A M (if awake) teacupful of warm milk
8 A M one helping of fine oatmeal porridge made with milk
cornflakes and milk egg lightly boiled poached, scrambled or as
omelette Bread and butter with jelly marmalade, honey or syrup
Teacupful milk flavoured with weak tea
10 A M teacupful milk flavoured with 'Ovaltine,' 'Horlicks
or 'Milo Plain biscuits or rusks
NOON one helping of egg or cheese dish, fresh fish, tripe, brains,
or chicken Mashed potatoes sieved vegetable
2 P M one helping of milk pudding, ice cream, light sponge
pudding or jelly
4 P M teacupful milk flavoured with weak tea Bread and
butter with jelly jam, honey or syrup Sponge cake or plain biscuits
6 P M one helping of vegetable soup (made with milk), egg or
cheese dish, fresh fish tripe, brains or chicken Bread and butter
8 P M as at 2 P M
10 P M as at 10 A M

Convalescent diet Two hourly feeds from 6 A M to 10 P M

6 A M 10 A M and 10 P M feeds as in basic diet
8 A M one helping of fine oatmeal porridge and milk cornflakes
and milk, egg, boiled poached scrambled or as omelette grilled
bacon soft roes or fishcake Bread and butter with jelly marmalade,
honey or syrup Weak freshly made tea with teacupful of milk
NOON one helping of egg or cheese dish fresh fish tripe brains
chicken, rabbit, ham lamb, or mutton (minced if tough) Mashed
potato Sieved vegetable
2 P M one helping of milk pudding, ice cream light sponge
pudding or sieved fruit
4 P M weak freshly made tea with teacupful milk Bread and
butter with jelly, jam, honey, or syrup Sponge-cake or plain
biscuits

6 P M   first course as at midday
8 P M   as at 2 P.M

Inpatients on the almost normal diet were given the same diet throughout

Almost normal diet

6 A M (if awake) tea with milk and sugar as desired
8 A M one helping of egg boiled, poached, or scrambled, grilled bacon or fish Bread and butter with marmalade Tea with milk and sugar as desired
10 A.M milk drink, flavoured as desired, or 'Bovril' Biscuits
Noon One helping of any fish, offal, chicken or any meat Potato mashed or boiled Green or root vegetables or salad Milk or sponge pudding ice-cream jelly, or fruit
3 30 P M bread and butter with any jam, honey, or lemon curd. Cake or biscuits Tea with milk and sugar as desired
6 P.M one helping of cheese or egg dish, fish, or any meat Green or root vegetables or salad (or helping of soup, cheese and biscuits) Bread and butter Sweet as at noon.
9 P M as at 10 A M

Fried foods were excluded from all three diets

Outpatients advised to adhere to a gastric diet were given the convalescent schedule described above, save that the 2 P.M and 8 P M feeds were combined with the midday and evening meals and the 4 P M and 10 P M feeds were brought forward $^1/_2$–1 hour

THE INEFFECTIVENESS OF SPLINTING IN THE TREATMENT OF ABDUCTOR PARALYSIS AT THE SHOULDER

W J W SHARRARD
M D Sheff, F R C S
CONSULTANT ASSISTANT ORTHOPÆDIC SURGEON, UNITED SHEFFIELD HOSPITALS, LATE CLINICAL RESEARCH ASSISTANT, INSTITUTE OF ORTHOPÆDICS, AND SENIOR REGISTRAR, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, LONDON

J KNOWELDEN
M.D Lond, D.P H.
LECTURER IN MEDICAL STATISTICS, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

FOR many years the application of an abduction splint has been a part of the accepted treatment of abductor paralysis at the shoulder (Jones and Lovett 1929)

The principle aims of splinting are as follows

(1) To relax the deltoid muscle and thereby to encourage its recovery

(2) To prevent the development of laxity in the capsule and ligaments of the shoulder-joint

(3) To prevent adduction contracture

(4) To prevent scoliosis

(5) To prevent or treat œdema of the upper limb

(6) To assist the patient in the performance of certain actions, such as feeding himself

We assess here the value of splinting, in relation to these aims, in the treatment of abductor paralysis caused at the shoulder by poliomyelitis

Material and Method

This study is based on all the adequately documented records of patients with poliomyelitis seen between 1946 and 1953 by one of two observers, Mr D M Brooks and one of us (W J W S) The records contained complete muscle charts, and paresis or paralysis of one deltoid muscle or of both was detected by clinical examination six weeks after the onset of paralysis This group comprised 129 patients with both deltoids affected, and 101 with one deltoid affected, making 230 patients and 359 affected muscles The two observers used the same technique of assessment of muscle power throughout Records were made of the following items

(1) The power of the deltoid muscle and of other muscles of the shoulder and upper arm six weeks after the onset of the paralysis and on a second occasion at least eighteen months later The Medical Research Council (1942) scale of muscle grading was used. We were particularly careful, in our assessment of the deltoid muscle, to observe that the movement produced was true scapulo humeral movement and that the deltoid muscle was producing it Up to 60° of abduction can be produced by scapular rotation alone, and true abduction at the scapulo humeral joint can occasionally be produced by the supraspinatus muscle in the presence of complete paralysis of the deltoid muscle

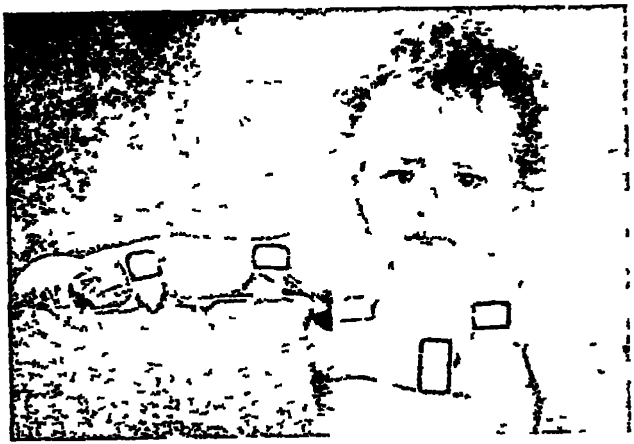

Fig 1—Standard abduction splint.

(2) The passive mobility of the shoulder joint, recorded as (*a*) normal, (*b*) laxity, in which the humeral head could be moved passively in the sagittal plane, (*c*) laxity subluxation, in which the humeral head could be moved passively in the vertical and sagittal planes, (*d*) mild contracture, in which total passive abduction of the upper arm was not full but was more than 90°, or (*e*) severe contracture, in which passive abduction was limited to less than 90°

(3) The duration of continuous or almost continuous respirator treatment and the existence of respiratory embarrassment that contra indicated the use of an abduction splint

(4) The presence of œdema in the upper limb

(5) The presence of scoliosis

(6) The duration of splinting in abduction

Treatment Groups

During the acute stage of poliomyelitis it was the usual practice, in the infectious diseases hospitals in which most of the patients were treated, to support an upper arm affected by poliomyelitis in abduction by suitably placed pillows or sandbags except where treatment in a respirator prevented this When a patient was admitted to the Royal National Orthopædic Hospital, one of the following regimes of treatment was prescribed

Group A, the deltoid muscle had been severely affected (*M.R C grade 0, 1, or 2*) 98 cases Splinting in abduction was continued either by an abduction splint (fig 1) when the patient was ambulant or sitting or by pillows when he was recumbent Adduction of the upper arm was allowed only during periods of active physiotherapy Splinting was continued for at least four months and in many instances for up to three years, the average time being twenty months This method was used in two-thirds of the patients admitted before 1950 but progressively less after this time

Group B, the deltoid muscle had been severely affected (*M R C grade 0, 1, or 2*) 118 cases No splinting in abduction was attempted A simple sling was used for comfort or convenience This group became relatively larger when a number of surgeons at the Royal National Orthopædic Hospital began to suspect that splinting in abduction was not essential for recovery of the deltoid muscle The admission of a patient to a bed in the charge of a surgeon who did or did not advocate splinting depended only on the chance vacancy at the time of request for admission When splinting was considered at all it was more likely to be prescribed where the initial deltoid grade was 0 rather than 1 and 2, and when the involvement was unilateral rather than bilateral

TABLE I—RECOVERY OF DELTOID MUSCLES IN GROUPS A (SPLINTED) AND B (UNSPLINTED)

—	Initial grade	Final grade						Total	Proportion showing recovery of 1 or more grades (%)
		0	1	2	3	4	5		
Group A (splinted)	0	71	6	5	2	—	—	84	15
	1	—	—	—	5	5	—	10	100
	2	—	—	—	1	3	—	4	100
Group B (unsplinted)	0	34	9	10	2	1	1	57	40
	1	—	—	2	19	5	2	28	100
	2	—	—	—	5	22	6	33	100

Group C, the deltoid muscle had been severely affected (M R C grade 0, 1, or 2) 17 cases Splinting in abduction was begun as in group A but, for various reasons, was discontinued before the fourth month These cases could not be considered as having been treated in either group A or B and were therefore analysed separately

Group D, the deltoid muscle had been severely affected (M R C grade 0, 1, or 2) and the patient had suffered respiratory weakness for which a mechanical respirator had been used 40 cases These patients could not wear an abduction splint, since there was not a free choice to splint in these cases, they were analysed separately

Group E, the deltoid muscle had been moderately or mildly affected (M R C grade 3 or 4) 86 cases No splinting in abduction was ever used after the sixth week in these cases

All the patients, whether splinted or not, were given similar treatment by passive movements to the shoulder-joint and by active exercises for the deltoid and other muscles of the upper limb (if working) up to, but not beyond, the point of fatigue

TABLE II—RECOVERY OF PARALYSED DELTOID MUSCLES IN GROUPS A AND B IN RELATION TO AGE

—	Age (yr)	Final grade						Total	Proportion showing recovery of 1 or more grades (%)
		0	1	2	3	4	5		
Group A (splinted)	0–4	41	2	1	2	—	—	46	11
	5–14	23	4	3	—	—	—	30	23
	15 or more	7	—	1	—	—	—	8	13
Group B (unsplinted)	0–4	12	2	3	1	—	1	19	37
	5–14	8	2	4	—	—	—	14	43
	15 or more	14	5	3	1	1	—	24	42

Recovery of Deltoid Muscle

The final grades reached by deltoid muscles in groups A and B are shown in table I There was little difference between the recovery in splinted and unsplinted cases when the deltoid muscle was acting at grade 1 or 2 at six weeks When the deltoid muscle was paralysed (grade 0) at six weeks, recovery was considerably better in the unsplinted than in the splinted cases Of the unsplinted muscles 40% (23 out of 57) showed some recovery compared with only 15% of the splinted muscles (13 out of 84) To test the validity of this conclusion analyses were made in relation to four other factors which might have influenced the recovery of the deltoid muscle

(1) *Age*—Muscle recovery in poliomyelitis is known to be more rapid and slightly greater in infants and children than in adults (Sharrard 1955) In the age distribution of groups A and B (table II) there is a predominance of children under the age of 15 in the splinted group (A) and of adolescents and adults in the unsplinted group (B) This might be expected to affect adversely the recovery in group B, but an analysis of the recovery of paralysed deltoid muscles in relation to age shows that *in each of the three age groups* 0–4, 5–14, and 15 or more, muscles in the unsplinted group recover more frequently than those in the splinted group There were too few cases in groups A and B with initial deltoid power of grade 1 or 2 to make a similar analysis by age

(2) *Calendar Differences*—An analysis was made of the recovery of paralysed deltoid muscles in groups A and B in relation to the year of onset of the paralysis This analysis was necessary because the decision by some surgeons to abandon splinting was made before 1949 and by others in 1949 or later In the early part of the period under review most of the cases were splinted, whereas later more of them were not splinted It seemed important to show that any differences in the recovery of patients in the two groups were independent of differences from one year to another in the type of patient or *in the general severity* of the poliomyelitis The results (table III) show that in each of the periods before 1949 and 1949–52 group B had the advantage over group A The only exception to this pattern in individual years was in 1948, where the numbers of patients in each group were small and the advantage of group A over group B was insignificant

TABLE III—RECOVERY OF PARALYSED DELTOID MUSCLES IN GROUPS A AND B IN RELATION TO YEAR OF ONSET OF PARALYSIS

—	Years of onset	Final grade						Total	Proportion showing recovery of 1 or more grades (%)
		0	1	2	3	4	5		
Group A (splinted)	Pre 1949	34	1	4	—	—	—	39	13
	1949–52	37	5	1	2	—	—	45	18
Group B (unsplinted)	Pre 1949	10	3	2	—	—	—	15	33
	1949–52	24	6	8	2	1	1	42	43

The recovery of paretic deltoid muscles (grade 1 or 2) generally showed a slight advantage in favour of group B, but there were too few muscles to allow a satisfactory comparison to be made in individual years

(3) *Distribution of Affection in Limbs*—H D Darcus (personal communication) has found that, in healthy people, specific exercise training given to one upper limb produces a training effect in the opposite upper limb The recovery of unilateral and bilateral cases in groups A and B was analysed to exclude the effect of different treatments applied to the opposite shoulder The results (table IV) indicate that, whatever treatment was being given to the opposite limb, the advantage was still with the unsplinted group (B)

(4) *Severity of Paralysis*—Among muscles that are still paralysed six weeks after the onset of poliomyelitis there are some, probably over 60% in all, that have been completely and irrevocably denervated by loss of all the anterior horn cells that supply them These muscles cannot recover A useful indication of the severity of the lesion affecting the motor nucleus of a given muscle, and hence its potentialities for recovery, can be obtained from an examination of the power of muscles supplied by the same spinal segments (Sharrard 1954)

A recovery index was calculated for each deltoid muscle It consisted of the sum of the grades of eight muscles that take some supply from the 5th and 6th cervical spinal nerve roots supraspinatus, infraspinatus,

TABLE IV—RECOVERY OF PARALYSED DELTOID MUSCLES IN GROUPS A AND B IN RELATION TO DISTRIBUTION OF AFFECTION IN ONE OR BOTH LIMBS

—	Distribution of affection	Final grade						Total	Proportion showing recovery of 1 or more grades (%)
		0	1	2	3	4	5		
Group A (splinted)	Unilateral	43	1	2	1	—	—	47	9
	Bilateral in same treatment groups	13	3	1	—	—	—	17	24
	Bilateral in different treatment groups	15	2	2	1	—	—	20	25
Group B (unsplinted)	Unilateral	4	2	1	—	—	1	8	50
	Bilateral in same treatment groups	27	5	7	2	—	—	41	34
	Bilateral in different treatment groups	3	2	2	—	1	—	8	63

TABLE V—RECOVERY OF PARALYSED MUSCLES IN GROUPS A AND B IN RELATION TO RECOVERY INDICES

—	Recovery index	Final grade						Total	Proportion showing recovery of 1 or more grades (%)
		0	1	2	3	4	5		
Group A (splinted)	0–9	56	—	—	—	—	—	56	0
	10–19	13	4	3	2	—	—	22	41
	20–29	2	2	2	—	—	—	6	67
Group B (unsplinted)	0–9	28	3	2	1	—	—	34	18
	10–19	5	2	7	1	1	—	16	69
	20–29	1	4	1	—	—	1	7	86

pectoralis major, teres major, subscapularis, biceps brachii flexor carpi radialis and pronator teres Table V analyses the recovery of paralysed deltoid muscles in relation to these indices and shows that, at all levels of the index, recovery in the unsplinted group B was superior to that in the splinted group A Similar analyses were made for deltoid muscles of initial grades 1 and 2 but with the small numbers available no consistent or significant advantage was seen in either treatment

Combined analyses were also made of recovery in relation to age and recovery index, distribution of paralysis and recovery index, and year of onset and recovery index The detailed results are not given here, since they only confirm the conclusions stated above

The final grades reached by deltoid muscles in groups C and D are shown in table VI Group C behaves rather more like group B than group A, though it is too small to show significant deviation from either

TABLE VI—RECOVERY OF DELTOID MUSCLES IN GROUP C (SPLINTED LESS THAN 4 MONTHS) AND IN GROUP D (UNSPLINTED WITH RESPIRATORY EMBARRASSMENT)

—	Initial grade	Final grade						Total	Proportion showing recovery of 1 or more grades (%)
		0	1	2	3	4	5		
Group C	0	8	3	2	—	—	—	13	38
	1 and 2	—	—	—	—	4	—	4	100
Group D	0	18	5	5	2	—	—	30	40
	1 and 2	—	—	3	3	3	1	10	100*

* The 3 cases with final grade 2 were initial grade 1

Recovery in group D appears to be as good as, or better than, in groups A or B, and detailed analysis showed this most clearly for paralysed deltoid muscles with low indices of recovery As regards paralysed muscles with all degrees of recovery index the proportion of group-D cases showing some improvement is 40% (12 out of 30), the same as in group B (23 out of 57) This group is interesting in showing that a position of adduction during the acute stage, though undesirable because of the liability of develop adductor contracture of the shoulder, does not seem to prejudice the ultimate recovery of the deltoid muscle

Conclusion—From these results it appears that splinting in abduction does not aid recovery of the deltoid muscle and may where the paralysis is severe actually discourage it

These results have received independent confirmation in a study of muscle recovery (Sharrard 1955) in which individual muscles of the upper and lower limb except the deltoid muscle and certain muscles in the shoulder region, showed identical curves of recovery In these the recovery was slower than the average in other muscles up to the sixth month but was greater at the tenth month Almost all the cases in that series were splinted, the late spurt of recovery coincided with the time when many of the splints were discarded

Laxity of Shoulder-joint

Without exception increased passive mobility of the shoulder-joint was present only if the deltoid muscle had remained paralysed Furthermore, the impression gained during the clinical examination of these cases was that laxity of the shoulder joint was often associated with severe paralysis of other muscles that play a part in holding the head of the humerus in the glenoid cavity A shoulder index was calculated for each case it consisted of the sum of the grades of eight muscles that act in this way deltoid supraspinatus infraspinatus, pectoralis major teres major, subscapularis, biceps brachii and long head of triceps

Any case in which the index was less than 10 was extremely likely to have a lax shoulder-joint, unless an adduction contracture had been allowed to develop during the acute stage of the poliomyelitis When the index was more than 14 laxity was uncommon, and when it was more than 24 laxity was never observed

TABLE VII—PASSIVE MOBILITY OF SHOULDER-JOINT IN GROUPS A AND B IN RELATION TO SHOULDER INDICES

Passive mobility	Shoulder index					
	0–9		10–19		20 –	
	A	B	A	B	A	B
Laxity-subluxation	31	10	3	—	—	—
Laxity	9	6	5	—	—	—
Normal	2	2	14	17	31	78
Mild contracture	1	2	2	1	—	2
Total	43	20	24	18	31	80

To assess the effect of splinting in abduction, cases in groups A and B at the same level of shoulder index were compared (table VII) At the critical index levels between 10 and 19 laxity subluxation and laxity were observed in 8 of the 24 splinted (group A) and in none of the 18 unsplinted (group B) Thus it may be that splinted cases suffer a double disadvantage not only do they recover less completely and hence become more likely to develop laxity at the shoulder-joint, but also, even with such muscle power as is regained, they may be more liable than unsplinted cases to develop laxity.

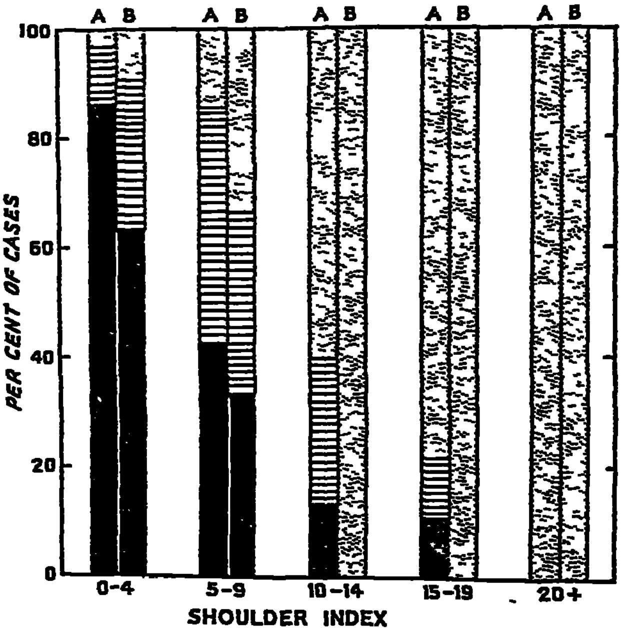

Fig 2—Relationship between shoulder index and laxity of the shoulder-joint in groups A and B *black*, laxity subluxation, *hatched*, laxity *stippled*, no laxity

The relationship between shoulder index and laxity, and the relative incidence of this condition in muscles in groups A and B are illustrated in fig 2

Conclusion —Splinting in abduction does not reduce or prevent laxity of the shoulder in the presence of weak scapulo-humeral muscles, but in some cases it increases it Lack of splinting does not increase laxity, which is primarily due to paralysis of muscles that help to maintain the head of the humerus in relation to the glenoid cavity

Adduction Contracture at Shoulder-joint

A mild adduction contracture was observed in 3 cases in group A (splinted), 5 cases in group B (unsplinted), and 1 case in group C (temporarily splinted)—an incidence of 3%, 4%, and 6% respectively In contrast to laxity, there was no evidence that contracture in these groups was related to the recovery index In group D (unsplinted, respiratory embarrassment), however, 18 shoulder-joints showed a severe contracture and 14 a mild contracture, a combined incidence of 80% (table VIII)

TABLE VIII—PASSIVE MOBILITY OF SHOULDER JOINT IN GROUP D IN RELATION TO DURATION IN TANK RESPIRATOR

Passive mobility	Time in respirator			
	<4 weeks	4–7 weeks	8 weeks or more	Total
Severe contracture	0	4	14	18
Mild contracture	4	10	0	14
Normal	6	2	0	8
Total	10	16	14	40

Since all the patients in this group had spent some time in a tank respirator, it is reasonable to infer that the limitation of movement was due to the position of adduction of the shoulder and to the fact that it was impossible to give adequate passive movements to the joints during the acute stage of the poliomyelitis Table VIII shows that the degree of contracture was related to the duration of more or less continuous respirator treatment Adduction contracture never increased or developed in a shoulder joint in any case in which it was not present at the initial examination six weeks after the onset of the paralysis No abnormality of passive movement of the shoulder was observed in group E (unsplinted, mildly affected)

Conclusion —Adduction contracture arises in cases in which the upper arm lies by the side and adequate passive movements cannot be maintained during the acute stage of the poliomyelitis, after the sixth week splinting in abduction is unnecessary to prevent a contracture from developing in a mobile joint

Scoliosis

In 39 patients the paralysis of one shoulder was severe (a recovery index of 9 or less) while the muscles of the opposite shoulder and in the remainder of the body showed no clinical paralysis Such a distribution of paralysis has been said to cause a thoracic scoliosis because of the unequal muscle pull on the two sides of the body exerted by muscles passing between the trunk and the upper limbs Not a single structural scoliosis was found even in cases examined six years after the onset of the paralysis, whether a splint had been worn or not In 10 cases a mild postural curvature of not more than 15° was present, in only 1 case was there a postural curvature of greater degree than this, and the curve was in the opposite direction to that which might have been anticipated from the site of the paralysis It was almost certainly due to the wearing of an abduction splint and disappeared a few weeks after the splint was discarded Eighteen other patients developed a structural scoliosis, in all of them the trunk muscles, especially the intercostal or lateral abdominal muscles, had been asymmetrically affected This confirms an observation first made by J I P James (personal communication)

Conclusion —Neither shoulder girdle paralysis nor splinting in abduction has any influence on the development or prevention of structural scoliosis in poliomyelitis

Œdema

No œdema was found in any upper limb in this series after the sixth week

Splinting as an Aid to Function

Whatever the eventual recovery of the deltoid muscle, the opinion of many patients who had worn a splint was that the limb was much more useful after the splint had been discarded The splint was regarded by the majority as an evil necessary to obtain recovery Exception must be made in one limited category patients in whom bilateral abductor paralysis at the shoulder is combined with weakness of elbow flexion with the result that the forearm cannot be raised against gravity In such a patient the upper limbs lie by the side, and he cannot make the best use of any muscles that have remained active in the forearm and hand, because he cannot bring either hand up to waist level After a time he develops trick methods of placing the hand where he wishes it to lie, but, as a temporary expedient, an abduction splint angled at 45° rather than 90° will raise the elbow to a level from which weak elbow flexors can flex the joint This use for an abduction splint is especially indicated in infants or young children in whom muscle re-education mainly depends on spontaneous activity and play

We must emphasise that a splint for this purpose differs in principle and in design from that shown in fig 1 Its function is to act as a platform rather than as a rigid splint A "lively" splint of the Capener (1949) type to which the limb is not tied is the most appropriate, it is not intended that it should be worn at all times but only as required In older children or in adults with bilateral paralysis it is occasionally useful but it is rarely indicated in unilateral paralysis Almost all patients, however young, eventually learn to facilitate activity in the paralysed limb by putting it into a useful position with the opposite hand

Discussion

The deleterious effects of over stretching of paralysed muscles was recognised by Lovett (1915) Many of the splints used in the treatment of the paralysis of poliomyelitis—e g, cock-up splints in paralysis of the wrist extensor muscles and apparatus for control of the paralysed foot—have been designed to prevent overstretching of muscles as well as to prevent deformity and aid function We do not deny this principle, indeed on several occasions one of us has witnessed late return of power in paralysed muscles following correction of deformity or after transplantation of powerful antagonist muscles

That the converse is true—i e, that relaxation of a muscle is necessary for its recovery—has never been demonstrated The recovery of the triceps suræ in poliomyelitis and in injuries to the sciatic nerve (Seddon 1949) in spite of the application of toe raising springs, the recovery of hamstring muscles, although the knee is splinted in extension, and numerous other examples suggest that relaxation is not essential for muscle recovery

Studies of the physiology of isolated muscle (Evans and Hill 1914, Doi 1921) show that an optimal initial tension is necessary for the development of maximal contraction in muscle In the body reflex mechanisms operating through muscle spindles and other proprioceptors enhance this action Provided that the principles of the prevention of deformity do not conflict with it, a mid-position of a joint that leads to moderate tension in the muscles controlling it is likely to encourage recovery

At the shoulder-joint all parts of the deltoid muscle are under optimal tension when the upper arm lies in the habitual position by the side of the body, the position of maximal stretch for the middle fibres of the muscle is with the upper arm fully adducted across the chest, and for the anterior and posterior fibres is with the upper arm abducted and extended or flexed respectively The position of the upper arm by the side therefore seems to be the ideal one for recovery of the deltoid muscle, and our results support this view

That the laxity of the shoulder-joint increases in proportion to the degree of paralysis in the scapulo humeral musculature is only to be expected, since one of the main actions of these muscles is to retain the humeral head in apposition with the glenoid cavity When the shoulder is abducted, the shape of the articular surface of the head of the humerus is such that all except the superior fibres of the capsule of the shoulder-joint are stretched, this may account for the increased joint laxity which we found in the splinted cases When the arm is by the side, only the superior fibres of the capsule are liable to be stretched by the weight of the limb, when, in a severe paralysis, this is likely to happen, a simple sling is adequate to minimise it

Provided that full passive mobility of the shoulder is present six weeks after the onset of the paralysis and is maintained by a single daily manipulation after this time, no contracture will develop, even though the arm lies by the side Before this time a position of abduction at the shoulder and the maintenance of as much mobility as is possible are essential Since the patient is usually confined to bed during most of this critical period, it is sufficient to support the limb in abduction on a pillow, and an abduction splint is inappropriate Only those patients who can become ambulant before a month require an abduction splint as a temporary measure to ensure that the adductor muscles of the shoulder do not shorten, and to guard against the development of œdema in the hand

There is no need to discuss here the inconvenience of splinting in abduction, the projecting encumbrance is a nuisance alike to the child and the adult and may be a positive danger to others in crowded places The position of the forearm and hand in an abduction splint is only useful for one purpose, that of feeding, since most manual activities are carried on at the level of the waist, splinting in 90° of abduction considerably diminishes the range of usefulness of the forearm and hand If, when the patient is confined to bed, he can feed himself better with the shoulder in abduction, an appropriate arrangement of vertical slings and springs produces the same effect as an abduction splint but allows much greater mobility without constraint to the chest

Conclusion —Except in the acute stage of poliomyelitis and in certain special circumstances in the convalescent stage, splinting in abduction is unnecessary and should be discontinued in the routine treatment of abductor paralysis at the shoulder

Summary

This study is based on 359 upper limbs in which some degree of abductor paralysis at the shoulder was present six weeks after the onset of acute poliomyelitis Records were made of the power of the deltoid and other muscles of the shoulder and upper arm, of the passive mobility of the shoulder joint, and of the function of the upper limb at this time and not less than eighteen months later The final state of cases in which an abduction splint had been used was compared with that in cases in which no splint had been used after six weeks from the onset of the poliomyelitis

The recovery of deltoid muscles paralysed (M R C grade 0) at the initial assessment was found to be diminished by splinting in abduction The recovery of paretic muscles (grades 1 and 2) appeared to be unaffected by splinting in abduction

The incidence of laxity of the shoulder-joint was shown to be related to the severity of the paralysis of the scapulo humeral muscles, this laxity was increased by splinting in abduction

Adduction contracture, if not already present, did not develop after six weeks in unsplinted shoulders that were passively mobilised daily In the acute stage of the poliomyelitis, on the other hand, immobilisation of the upper limb by the side, as happens when continuous respirator treatment is necessary, produced a more or less severe adduction contracture

Structural scoliosis was never found when the paralysis had affected the upper limb musculature alone, even where this paralysis was severe and unilateral Splinting in abduction to prevent scoliosis is therefore unnecessary

Occasionally a partially abducted position of the shoulder may allow better function of the remainder of the upper limb If so, a modified splint may be useful in bilateral abductor paralysis in young children

The principles underlying the use of abduction splints are discussed, it is concluded that, except in the acute stage of poliomyelitis and in special circumstances in the convalescent stage, splinting in abduction is unnecessary and sometimes harmful

We wish to thank the Medical Research Council for a personal grant to one of us (W J W S), Mr D M Brooks, who examined many of the patients at the onset of their paralysis, Prof Bradford Hill and Mr H. J Seddon for their help and guidance, and all the surgeons of the Royal National Orthopædic Hospital for permission to study these patients

It is extremely difficult to assess reliably the value of any form of treatment in leptospirosis, because the severity, course, and complications of this disease vary greatly, even among patients infected by identical leptospiral serotypes There is still doubt about the value of antibiotics in leptospirosis, as is well shown by the conflicting opinions so far published.

Before the advent of antibiotics, the most widely used form of therapy was immune serum Inada et al (1916) were the first to try it in experimental infections in guineapigs, and later therapeutically in man Serum was effective in protecting guineapigs when given with an inoculation of *Leptospira icterohæmorrhagiæ* Walch Sorgdrager (1939) reviewed the results of serum treatment in cases examined serologically at the Institute of Tropical Hygiene, Amsterdam No definite evidence of its value was found, although there was a strong clinical impression that it was useful

---

* Present address Department of Medicine St Thomas's Hospital Medical School London

Most of the antibiotics now available have been examined for their effect on leptospirosis both in experimentally infected animals and in man At first sight the results of these experiments are encouraging

Previous Experience with Antibiotics

PENICILLIN

Experimental Observations

Alston and Broom (1944) and Chang (1946) found that penicillin inhibited the growth of *L icterohæmorrhagiæ* cultured in Fletcher's medium

Heilman and Herrell (1944) found that guineapigs artificially infected with *L icterohæmorrhagiæ* were protected by penicillin administered seventeen to twenty four hours after inoculation Alston and Broom (1944) agreed that penicillin administered eighteen hours after inoculation reduced the death-rate Augustine et al (1944) gave penicillin to guineapigs on the fourth day after inoculation, when jaundice was present, but observed no benefit They next gave the antibiotic thirty eight hours after inoculation There was no difference in the mortality-rate, but no animal became jaundiced, and life was prolonged Chang (1946) repeated these experiments, but gave penicillin on the third, fourth, fifth, and sixth days after inoculation Penicillin had a therapeutic effect if administered before the onset of jaundice, but once jaundice had appeared penicillin was useless This was similar to the findings of Larson and Griffiths (1945)

Throughout most of these experiments, difficulties arose over the possible toxic effects of penicillin on guineapigs It was noticed that some of the animals receiving penicillin died without evidence of leptospirosis or of any other disease Dunn and Thompson (1953) therefore tried the effect of penicillin on experimental infection in hamsters Treatment was started twenty four hours after inoculation, and it protected the animals against death But specimens of their livers and kidneys subinoculated into other hamsters produced leptospirosis, even when the inoculated animals were receiving sixteen times the amount of penicillin necessary to protect them against death

These experiments showed that penicillin must be given early if it is to be effective—probably within twenty-four hours after inoculation Even then, leptospiræ may be recovered from the liver during and after treatment (Chang 1946, Dunn and Thompson 1953) If these findings are applicable to man, treatment would have to anticipate the dissemination and multiplication of leptospiræ in the tissues, which normally takes place during the incubation period of four to twelve days In practice, treatment is seldom started before the fourth day of the disease—and often later

Clinical Observations

It is difficult, especially with a small number of cases, to decide whether an antibiotic has influenced the natural course of leptospirosis By the time the patient has been admitted to hospital, his illness diagnosed, and antibiotic treatment started, a natural improvement in his condition is usually starting

There have been many reports of the beneficial effects of penicillin in leptospirosis, based on a small number of treated cases (Bulmer 1945, Carragher 1945, Cross 1945, Baber and Stewart 1946, Niemi 1946, Moreau et al 1947, Patterson 1947, MacKay-Dick and Watts 1949, Dinaraj 1950, Lawson 1951, Suchett Kaye 1951)

Hutchinson et al (1946) reported a series of cases in Italy The illness was severe, and all patients were jaundiced 6 patients received penicillin in doses of 15,000 units three hourly, to a total of 600,000–660,000 units Hutchinson et al considered that penicillin had no significant effect on the disease, but it is difficult to draw any definite conclusions from this small series because treatment was started after the onset of jaundice, and the penicillin dosage was low by present day standards

Broom (1951) reviewed the results of penicillin therapy in 206 patients treated in several hospitals throughout Britain The mortality in this group did not differ significantly from that in 259 patients who were not given penicillin

Recently Doherty (1955) has recorded a larger series of cases treated with penicillin in dosages of 100,000–500,000 units three hourly Doherty concludes that penicillin in large doses significantly reduced the duration of fever Unfortunately this series was highly selected There were only 8 controls out of 111 cases, and the patients were treated at eight different hospitals, most of which used their own antibiotic regime Doherty also says that the time of temperature taking and the use of antipyretics varied from one hospital to another Finally, the observers were presumably aware of the type of treatment the patient was having This is important because the practitioners in the area were strongly in favour of penicillin therapy

CHLORAMPHENICOL AND OTHER ANTIBIOTICS

Experimental Observations

Chloramphenicol has given less encouraging results

Schlipkoter and Beckers (1951) showed that all the species they tested had considerable resistance, especially *L autumnalis* They anticipated that chloramphenicol would have no therapeutic action in man Dunn and Thompson (1953) found that in hamsters chloramphenicol gave no protection against death

Aureomycin and *oxytetracycline* have been found to be effective in vitro (Heilman 1948, Ormsbee 1953, Schlipkoter and Gram 1952) and in vivo provided they are given early (Schlipkoter and Beckers 1951)

Clinical Observations

Hall et al (1951) reported on 79 cases from an epidemic of leptospirosis in Puerto Rico

Antibiotic trials were made in sequence, one type of treatment finishing before another was started 12 patients who were not given antibiotics acted as controls, and the remainder received either *penicillin, streptomycin, aureomycin* (chlortetracycline), *oxytetracycline*, combined *streptomycin and aureomycin*, or *cortisone and aureomycin*

No significant effect on the course of fever, jaundice, renal involvement, neurological manifestations, and leptospiræmia was observed Because six different methods of treatment were employed, the number of patients in each group was small

Doherty (1955) drew no definite conclusion about the value of *chloramphenicol* from his series of cases

Several workers have reported that *aureomycin* and *oxytetracycline* are beneficial (Batchelor and Todd 1950,

Total	83	31	21	31

* A new serotype isolated in Australia by Smith et al (1954)

TABLE II—AVERAGE DAY OF ILLNESS ON WHICH PATIENTS WERE ADMITTED AND TREATMENT WAS STARTED

Treatment group	Admitted (day)	Treatment started (day)
A (controls)	4 0	4 0
B (penicillin)	3 4	4 7
C (chloramphenicol)	4 0	5 0

Brainerd et al 1949, Liebowitz and Schwartz 1951 Lurie 1949, Stagg and Liebowitz 1951, Whitehouse 1952) Nearly all these reports were based on a few cases, and are open to the same criticisms that apply to the reports on treatment with penicillin

Materials and Methods

Leptospirosis is quite common among British troops engaged in jungle operations in Malaya The mortality is very low, only 2 deaths were reported among 160 confirmed cases notified in 1954 1 of these 2 patients had malaria as well, and there was a certain amount of doubt about the diagnosis in the other (D G Lewis, personal communication) The disease is not severe, and of the present series only 4% became jaundiced and 5% had oliguria or anuria (oliguria is here defined as a urinary output of 10 oz or less in twenty-four hours)

In the present series the patients, all of whom were men, had been admitted to one of two military hospitals in Malaya Their ages ranged between 18 and 35 years, the average being 21 71 patients were British, 9 were Gurkhas, 2 were Malays, and 1 was Chinese The predominance of Europeans is not due to selection but reflects the lower incidence of leptospirosis among Asian troops

TABLE III—AVERAGE TIME FROM ONSET TO FREEDOM FROM SYMPTOMS AND SIGNS

Treatment group	Symptom free (days)	Sign free (days)	Apyrexial (days)	Symptom free and sign free (days)
A (controls)	9 4	9 9	9 0	10 8
B (penicillin)	8 2	9 5	7 6	9 7
C (chloramphenicol)	8 9	10 0	8 8	10 5

Paired specimens of serum were sent to Dr J C Broom, of the Wellcome Laboratories of Tropical Medicine, London, for agglutination tests In some cases blood was cultured in Fletcher s medium, and a few of the strains obtained were sent to Dr Broom for identification

It was possible to identify the serotype or serogroup in 50 out of 83 cases, either by agglutination or by culture In the remaining patients the agglutination tests were positive, but accurate identification of the serogroup was obscured by heterologous rises in titre

The patients were further subdivided into controls, and those receiving penicillin and chloramphenicol (table I)

The serotypes or serogroups among the controls were less easily identified In the few patients in whom jaundice or oliguria developed, no correlation with any particular serogroup was obtained

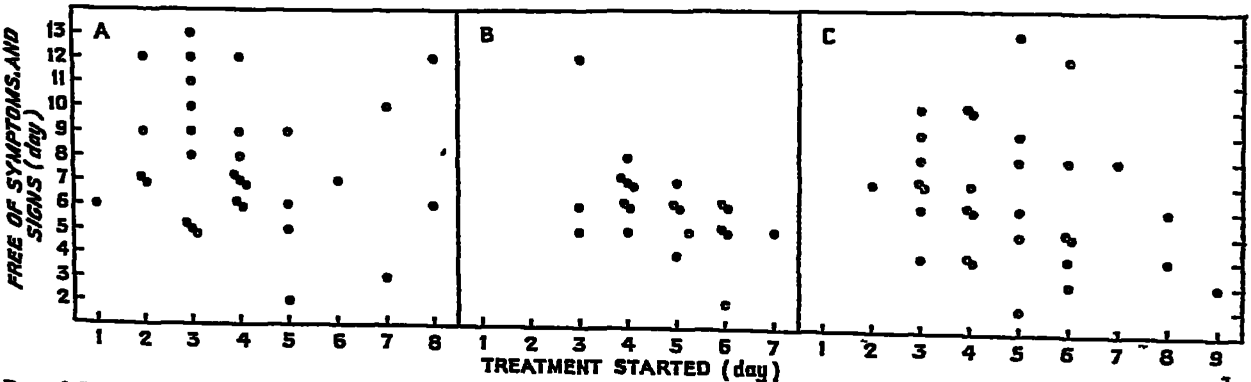
Patients were placed in rotation in one of three groups Patients in group A received no antibiotics and acted as controls Patients in group B were given penicillin 600,000 units six-hourly, and those in group C chloramphenicol 0 5 g six hourly Treatment was started as soon as the diagnosis was made Antibiotics were given for at least five days, and often beyond that until the patient had been afebrile and free of symptoms and signs for twenty-four hours The average duration of treatment in group B was six days, and in group C 6 2 days

TABLE IV—RESULTS CLASSIFIED ACCORDING TO WHETHER TREATMENT WAS STARTED ON OR BEFORE, OR AFTER, FOURTH DAY OF ILLNESS

Treatment group	Treatment started			
	On or before fourth day		On or after fifth day	
	No of patients	Av time from start of treatment till symptom-free and sign free (days)	No of patients	Av time from start of treatment till symptom-free and sign free (days)
A (controls)	22	8 2	9	6 7
B (penicillin)	10	6 9	11	5 0
C (chloramphenicol)	14	7 0	17	6 1

Symptoms and signs were recorded daily on a standard chart by one of two observers who were unaware of the group to which the patient had been allotted Subsequently, some cases were excluded because of an associated attack of malaria, or because the diagnosis was not confirmed This resulted in uneven numbers of patients appearing in each group, the numbers being group A (controls), 31, group B (penicillin), 21, and group C (chloramphenicol), 31 (total 83)

Table II shows the average day of illness when the patients were admitted, and the day on which treatment was started In the control group the day of admission was called the first day of treatment, which consisted in rest in bed, fluid replacement, and analgesics for pain This regime was also employed in groups B and C, but the day when antibiotics were first given was termed the day that treatment was started. There was a time-lag of approximately twenty-four hours in the start of treatment in groups B and C.



Days of illness on which treatment was started and patients became free of symptoms and signs in A controls, B patients treated with penicillin C, patients treated with chloramphenicol

Results

Table III shows the average time from onset of symptoms until the patients were symptom-free, sign-free, and apyrexial

There was no significant difference between the duration of illness in the three groups This is most convincingly shown in the last column of table III Symptoms and signs developing during a relapse are considered separately

The patients in each group are classified in table IV into those whose treatment was begun on or before the fourth day, and those whose treatment was begun on or after the fifth day Table IV shows that early treatment with antibiotics did not shorten the average length of the illness, in fact in all three groups the average number of days taken to become symptom-free and sign free was greater when treatment was started early This is confirmed by the accompanying figure, in which the day on which the patient became free of symptoms and signs after the start of treatment is plotted against the day on which treatment was started The wide scatter is not influenced by the antibiotics

"*After-peaks*" *of Pyrexia*

An "after peak" of pyrexia is here arbitrarily defined as any rise of temperature to 100°F or over, forty-eight or more hours after the patient first became apyrexial A few patients had transitory rises in temperature below 100°F unassociated with symptoms and signs, but these were regarded as insignificant

TABLE V—INCIDENCE OF JAUNDICE, OLIGURIA, AND ANURIA

Treatment group	No of patients with jaundice	No of patients with oliguria or anuria
A (controls)	2	2
B (penicillin)	Nil	1
C (chloramphenicol)	1	1

"After-peak" pyrexia occurred in only 14% of all the patients 6 were in group A (controls), 3 in group B (penicillin), and 3 in group C (chloramphenicol) The numbers are too small for any definite conclusions

Complications

Jaundice, and oliguria or anuria—Table V shows the incidence of these complications in each treatment group There was no significant difference between the three groups, but the numbers were too small for us to draw any definite conclusions from them

TABLE VI—BLOOD UREA LEVELS

Treatment group	Av day of illness blood urea first estimated	No of patients with blood urea estimated every third day	No of patients in whom blood urea rose after start of treatment
A (controls)	4 3	12	4
B (penicillin)	3 7	10	2
C (chloramphenicol)	3 3	11	4

Uræmia—In 33 patients admitted before the fifth day of their illness, the blood-urea level was estimated on admission and then every third day In 10 of these cases the level rose by 15 mg per 100 ml or more during treatment—the higher blood urea level always being above 40 mg per 100 ml The results are shown in table VI The numbers are small, but there is no significant difference between the distribution among the three groups.

Discussion

In this series no benefit was obtained from the administration of penicillin or chloramphenicol, and we suggest that these two antibiotics have no place in the treatment of leptospirosis in Malaya

This series included many mild cases, and complications were few. Because leptospirosis is common among troops in Malaya, the standard of diagnosis is high and few cases are missed, whereas in countries where the disease is rare it is mainly the more severe cases that are recognised This may partly account for the different descriptions of the severity of leptospirosis throughout the world In our series the serotypes were widely represented (table I), this suggests that if penicillin and chloramphenicol are of no value in the treatment of leptospirosis in Malaya, it is unlikely that they will prove useful elsewhere

Summary

A controlled trial of penicillin and chloramphenicol in the treatment of leptospirosis among British troops in Malaya is reported

Patients were placed in rotation in one of three groups One group of patients received no antibiotics and acted as control The second group received penicillin, and the third group received chloramphenicol

There were no significant differences between the three groups in the times taken to become symptom free and sign-free and apyrexial, or in the incidence of complications This was true even when treatment was started on or before the fourth day of the illness

Penicillin and chloramphenicol play no useful part in the treatment of uncomplicated leptospirosis in British troops in Malaya, and we suggest that these antibiotics are unlikely to be of value in the treatment of leptospirosis elsewhere

We thank Lieut General Sir Frederick Harris for permission to publish this paper, Colonel A P Trimble, consulting physician to the far eastern land forces, for his help throughout the trial, the sisters of the Q A R A N C for their coöperation in this work, and Dr J. C Broom for his help and advice

DUODENAL BIOPSY

MARGOT SHINER
M R C S
RESEARCH ASSISTANT, DEPARTMENT OF MEDICINE,
POSTGRADUATE MEDICAL SCHOOL OF LONDON

THE method of gastric biopsy by blind suction through a gastric biopsy tube (Wood et al 1949) has been safely applied to many patients (Doig 1954, Palmer 1954, Joske et al 1955) but has not hitherto been extended to biopsy of the duodenum.

It was thought that a modified tube might be passed beyond the pylorus to sample duodenal or even jejunal mucosa, and that this technique might be of diagnostic value in such conditions as steatorrhœa, Crohn's disease, "duodenitis," and dyspepsia without positive radiographic findings.

The main modifications required were greater length and a shorter head embedded in a rounded metal shield. X-ray control was essential in guiding the course of the tube.

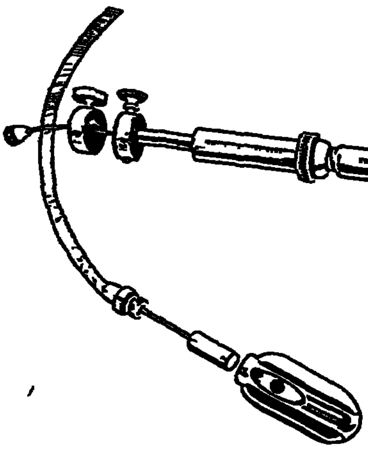

Fig 1—Tube 1: headpiece and tailpiece.

The histological findings of 12 successful duodenal biopsies are reviewed here.

Method and Patients Studied

The duodenal biopsy tube (fig 1) is a flexible tube, 128 cm long and 4·8 mm in diameter coated with plastic material to make it smooth and airtight. Its headpiece is a small tube 3·9 mm in external diameter, at whose centre is the circular biopsy aperture 3·1 mm in diameter. In this small tube the knife-cylinder is accommodated which is screwed to the wire running along the whole length of the instrument and ending in a small holder at the tailpiece. The small tube of the headpiece is embedded in a solid weighty elliptical nickel ball 12·3 mm in diameter to give smooth easy forward propulsion by gastric and duodenal peristalsis. The tailpiece contains the other end of the wire and the lateral exhaust-tube, to which a syringe or a pressure manometer can be attached to apply negative pressure.

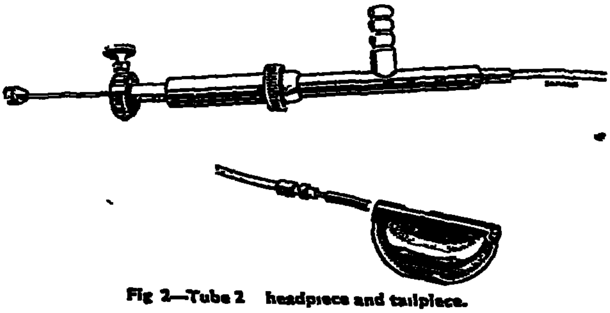

Fig 2—Tube 2: headpiece and tailpiece.

Fig 2 shows a second duodenal biopsy tube, which was used originally. It is as long as the first tube but only 2·7 mm in diameter. The headpiece is rather weightier and 14·2 mm in diameter. The biopsy aperture measures 2·3 mm in diameter and the small tube within the headpiece 3·1 mm in diameter. Both tubes have been used with about equal success.

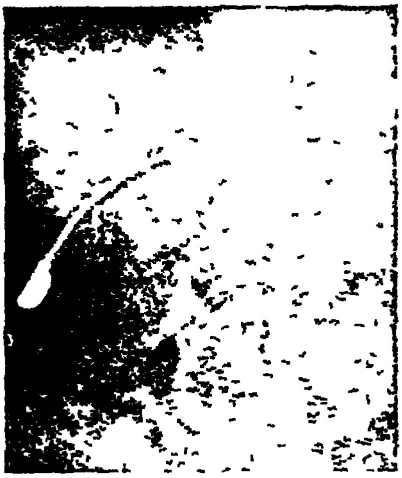

Fig 3—Headpiece of duodenal biopsy tube in first or second part of duodenum.

Samples were obtained from 12 patients with gastro-intestinal symptoms. In 7 the diagnosis was in doubt even after full radiographic and other studies. In the remaining 5, who had gastric ulcer (2), duodenal ulcer (2) and hiatus hernia (1), the instrument was used primarily for gastric biopsy; but, since there was no difficulty in passing the tube beyond the pylorus, duodenal biopsy was done as well. The procedure was carefully explained to the patients and permission obtained from all.

The fasting patient gargles with 2–3 ml of 1% amethocaine solution. The stomach need not be emptied beforehand, because gastric juice does not interfere with duodenal biopsy. With the patient lying relaxed on his left side with knees drawn up and head and trunk on the same level, the well-oiled tube is passed into the stomach. The tube is occasionally held up at the pharynx and the cardia; but this can easily be overcome by making the patient swallow and by exerting gentle pressure on the tube. When the stomach is reached, the head end of the tube is guided, under fluoroscopic control, by the palpating hands of the operator on the patient's abdomen. As soon as the required position in the duodenum is attained (figs 3 and 4) the biopsy is attempted. The wire is operated at the tailpiece to open the biopsy aperture, and a negative pressure of at least 25 inches Hg is applied. Then a sharp closing movement of the wire will secure the biopsy specimen within the knife-cylinder. If it is necessary to take samples from different levels, the position of the headpiece may be adjusted and the manœuvre repeated. Before the tube is withdrawn, its position is again checked fluoroscopically. After withdrawal the specimens are freed from the knife-cylinder and placed in 15% formol saline solution.

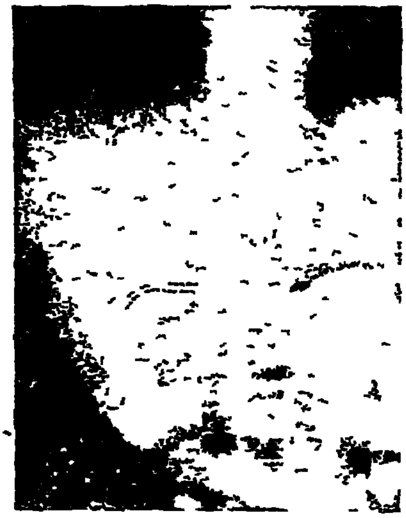

Fig 4—Headpiece of duodenal biopsy tube in second or third part of barium-filled duodenum.

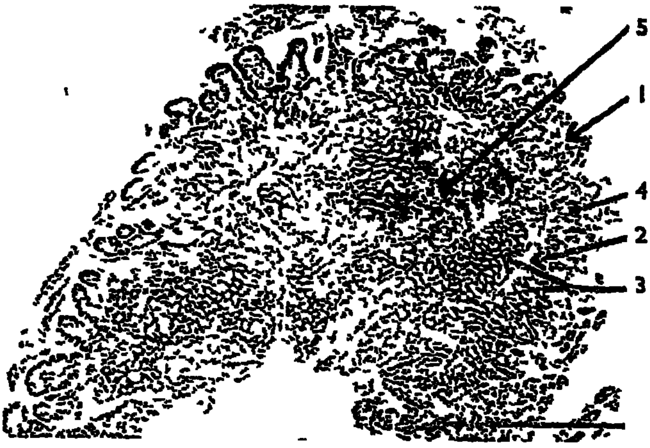

Fig 5—Type-1 biopsy specimen 1, villi, 2, muscularis mucosæ, 3, Brunner's glands, 4, crypts of Lieberkühn 5, hæmorrhage (Hæmatoxylin and eosin × 19)

or in formol calcium, and histological preparations are made The patient is given a light meal and closely observed for twenty-four hours No complications developed in the present 12 cases

Results

Duodenal biopsy was attempted in 19 cases and was successful in 12 of them Many of the earlier failures were due to inexperience and lack of practice The failures were due to inability either (*a*) to reach the duodenum or (*b*) to obtain specimens Inability to reach the duodenum was due to spasm at the pharynx, the cardia, or the pylorus Spasm at the first two sites was usually overcome when the patient relaxed, but spasm at the pylorus did not seem to be under voluntary control and caused failure in 2 patients Inability to obtain specimens when the duodenum was reached was responsible for 5 more failures and was probably due to earlier technical difficulties in the construction of the tubes

The size of the specimens was difficult to measure Usually several specimens were clumped together, and attempts to separate them before fixation may have broken them up The number of specimens obtained varied from 1 to 5 In size they compared well with those obtained by gastric biopsy The naked-eye appearances were those of small fleshy pinkish pieces of tissue held together by mucus The depth of the specimens varied according to their site, being deepest in the first part of the duodenum and becoming progressively less deep distally Of the 12 specimens 2 were not deep enough to warrant detailed histological description

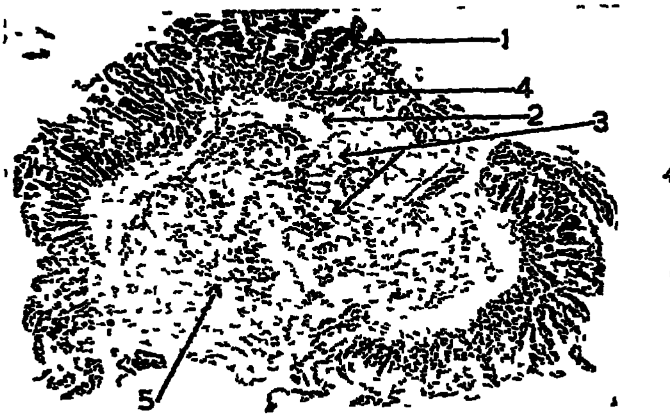
Histology

No correlation of the histological appearances of the duodenum with the clinical diagnosis has yet been attempted, nor does the number of biopsy specimens studied permit histopathological classification or comparison The over all histological appearances assumed three different patterns varying with the levels of duodenum from which the specimens were taken Some of the specimens showed typical Brunner's glands, whereas others showed the type of mucosa usually associated with the small intestine

Type 1—Of the 12 specimens 2 showed this histological pattern The site from which they were taken is shown in fig 3 The specimen shown in fig 5 comprises the full depth of mucosa and submucosa The villi are well marked though somewhat shorter and broader than those of type 2 (see below) Their surface epithelium contains columnar cells with goblet cells interspersed between them The stroma of the villi and lamina propria of the mucosal layer contains a moderate amount of lymphocytes, plasma cells, a few eosinophils, and an occasional polymorph The crypts of Lieberkühn and their glands lie in the mucosal layer and are continuous superficially with the surface epithelium and deeply with Brunner's glands They are composed of low columnar cells, Paneth cells, and argentaffin cells A thin layer of smooth muscle fibres, the muscularis mucosæ, separates the mucosa from the submucosa It is occasionally penetrated by a group of Brunner's glands, though most of these glands are found in the submucosa, which is rather deep containing numerous groups of Brunner's glands, characterised by their low columnar cells with clear cytoplasm and flat basal nuclei These groups of glands are separated by strands of fibrous tissue

Type 2—This type was seen in 3 specimens and differs from type 1 in possessing longer and narrower villi, denser cellular infiltration, and a rather thick layer of muscularis mucosæ In the specimen shown in fig 6 only a small group of Brunner's glands is evident at the centre, lying in the submucosa The type of cellular infiltration is similar to that described in type 1

Type 3—This type was seen in 5 specimens Fig 4 shows the site from which the specimen shown in fig 7 was taken, probably the third part of the duodenum Again, as in type 2, the villi are high and branching, and the muscularis mucosæ is rather thick and well developed Brunner's glands are not seen either above or below the muscularis mucosæ I have recently obtained several jejunal biopsy specimens from a patient who had previously undergone a Polya gastrectomy The histological appearances of these jejunal specimens resembled in every respect those seen in type 3 Possibly the lower part of the duodenum has the same histological pattern as the small intestine



ig 6—Type-2 biopsy specimen 1 villi 2 muscularis mucosæ 3, Brunner's glands in submucosa 4 crypts of Lieberkühn, 5 hæmorrhage (Hæmatoxylin and eosin × 23)

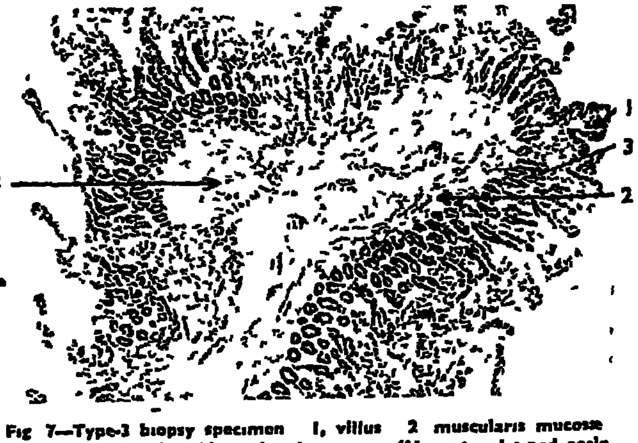


Fig 7—Type-3 biopsy specimen 1, villus 2 muscularis mucosæ 3, crypts of Lieberkühn 4 submucosa (Hæmatoxylin and eosin × 35)

Discussion

This technique has proved safe and satisfactory in obtaining duodenal specimens, but it has the disadvantage that the specimen is taken blindly and its exact position in the duodenum is uncertain If a little barium is given before the tube is passed, it may be possible to determine what part of the duodenum is being subjected to biopsy

As regards the construction of the two tubes, the advantage of tube 2 (fig 2) over tube 1 (fig 1) lies in possessing a larger and weightier headpiece on a narrower shaft The duodenum is reached with greater ease, and the long wire does not coil inside the narrow plastic tube The disadvantage lies in the smaller negative pressure obtained through this narrow tube Earlier failures to obtain specimens were attributed to this technical defect, so tube 1 was constructed with a greater diameter It was found that the wire tended to coil much more, but the size of the biopsy aperture and the improved suction were very satisfactory The range of movement of the knife cylinder to open and close the biopsy aperture is necessarily small and controlled at a point some distance away Moreover the tube, once in the desired position is not straight The curves of the tube vary from patient to patient, and there is no way of regulating the wire's movements beforehand It is therefore evident that a more certain way of knowing when the aperture is open is required Experience in handling the instrument has largely, if not entirely, overcome this difficulty

The risks attending duodenal biopsy are probably comparable to those attending gastric biopsy—namely, perforation of the pharynx, œsophagus, or stomach, and hæmorrhage, usually hæmatemesis Perforation has been reported in 1 of 589 cases (Coghill and Williams 1955), in none of 1226 cases (Joske et al 1955), and in none of 1000 cases (Doig 1954) Hæmatemesis is more common but rarely fatal it has been reported in 7 of 589 cases (Coghill and Williams 1955) and in 8 of 1000 cases (Doig 1954) No complications developed in my own series of 130 gastric biopsies, and in the present 19 attempts at duodenal biopsy

As already stated, 2 of the 12 successful duodenal biopsies did not yield enough tissue to warrant detailed histological analysis This is another difficulty peculiar to duodenal biopsy The gastric surface epithelium is smooth though thrown into rugæ, whereas the duodenum has large branching villi in continuous motion, with much debris and mucus overlying them Sometimes cellular debris and the tips of a few villi only are caught within the biopsy aperture Other specimens showed a satisfactory depth of mucosa, but the villi appeared "decapitated"

The three histological types described seem to represent different levels of duodenum Type 1 comes from the first and second parts of the duodenum and shows typical Brunner's glands Type 3 comes from the second and third parts of the duodenum and resembles intestinal mucosa A detailed study of the level at which one type of mucosa changes into the other is obviously necessary

Another point of interest for future studies arises from the part played by the duodenum, especially its lower end, in various diseases of the small intestine A jejunal biopsy specimen was obtained in 1 patient with a Polya gastrectomy Slight modification of the duodenal biopsy tube may enable us to reach the normally sited jejunum

Summary

A method of blind duodenal biopsy is described, and 12 biopsy specimens are discussed

The difficulties and the possible practical applications of the method are mentioned

The attendant risks are compared with those of gastric biopsy

No complications developed in 19 attempts at biopsy

My thanks are due to Dr Sheila Sherlock for stimulating and helpful criticism, the Genito Urinary Manufacturing Company, particularly Mr G Hawkins, for coöperation in constructing the duodenal biopsy tube, Miss E J Wernli for helpful assistance, Mr J G Griffin for the histological preparations, Mr F G Saunders for the drawings, and Miss R Klein for the photomicrographs

THE HOSPITAL STAPHYLOCOCCUS

A COMPARISON OF NASAL AND FÆCAL CARRIER STATES

J Brodie

JUNIOR HOSPITAL MEDICAL OFFICER

T Sommerville
M D Edin
LECTURER

From King's Cross Infectious Diseases Hospital, Dundee, and the Department of Bacteriology, Queen's College, St Andrews University

The frequency with which staphylococcal disease is acquired in hospital causes increasing concern (*Lancet* 1955a) It is widely held that the nasal carrier is the main source of infection in outbreaks of such disease Is this the whole truth? We draw attention here to the fæcal carrier as a potential source of infection in staphylococcal disease and point out that such a carrier is commonly also a nasal carrier

Brodie et al. (1955) emphasised the value of serological typing of staphylococci in the study of outbreaks of staphylococcal disease This method of typing was adopted in the present study The search for fæcal carriers was based on isolations from rectal swabs Confirmation that the source of these strains was the fæces, and *not* the skin of the buttocks, was obtained by a series of comparative tests of the nose, skin, and fæces

The simultaneous search for nasal and fæcal carriers was made in two dysentery wards in which there was an outbreak of staphylococcal disease at the time of the survey

Results of Survey

CARRIER STATE IN THE WARDS

Table I compares the "snapshot" picture of the carrier status at the start of the survey with that of patients on admission to and after one week's residence in hospital This table includes the results for nasal and fæcal strains The following points are to be noted

(1) The general picture obtained by the single "snap shot" is little different from that obtained from the group of patients examined after one week's stay in hospital

TABLE I—COMPARATIVE ANALYSIS OF CARRIER STATES

—	56 ward patients at start of survey		127 patients on day of admission		74 ward patients after 1 week in hospital	
	Nasal swab	Rectal swab	Nasal swab	Rectal swab	Nasal swab	Rectal swab
Coagulase-positive	23 (*41%*)	21 (*38%*)	26 (*20%*)	22 (*17%*)	28 (*38%*)	28 (*38%*)
No serotype ac/	16 (*29%*)	16 (*29%*)	8 (*6%*)	6 (*5%*)	20 (*27%*)	26 (*35%*)
Other serotypes	7	5	18	16	8	2

TABLE II—ANALYSIS OF SIMULTANEOUS ISOLATION FROM NASAL AND RECTAL SWABS

Total no	No with same sero type	No both ac/-	Resistance patterns of ac/					No with different sero types
			No both POCST*	No both POCCST†	No nasal/POCST rectal/POCCST	No both POCCS‡	Others	
63	50	43	12	4	15	4	8	13

* POCST resistant to penicillin, oxytetracycline, chlortetracycline, streptomycin and tetracycline, sensitive to chloramphenicol and erythromycin

† POCCST = POCST, except resistant also to chloramphenicol

‡ POCCS = POCST, except sensitive to tetracycline

(2) On admission, 20% (26/127) of patients were nasal carriers, compared with 38% (28/74) after one week in hospital

(3) 17% (22/127) were fæcal carriers on admission, compared with 38% (28/74) after one week in hospital

(4) 6% (8/127) were carriers of serotype ac/- of nasal origin on admission, compared with 27% (20/74) after one week in hospital

(5) 5% (6/127) of patients were carriers of serotype ac/- of fæcal origin on admission, compared with 35% (26/74) after one week in hospital

(6) Residence in hospital resulted in a fall in the prevalence of carriage of all serotypes other than serotype ac/- This applied to both nasal and fæcal strains

The results obtained by antibiotic sensitivity testing of serotype ac/- confirmed the general experience that one week's residence in hospital was associated with a high frequency of infection with cross resistant strains But, whereas nasal strains were resistant to penicillin, oxytetracycline, chlortetracycline (aureomycin), streptomycin, and tetracycline, fæcal strains were resistant to these antibiotics and also to chloramphenicol All strains isolated from patients after one week in the ward were sensitive to erythromycin

SIMULTANEOUS CARRIAGE IN NOSE AND INTESTINE

Of 63 patients no fewer than 50 were nasal and fæcal carriers at the same time Of these 50, 43 were carrying serotype ac/- The resistance patterns of these strains differed considerably Some nasal and fæcal strains showed the same resistance patterns, while others exhibited different patterns Indeed, in one group of 15 patients the fæcal strains were resistant to chloramphenicol and 5 other antibiotics, whereas the nasal strains, although resistant to the 5 antibiotics, were sensitive to chloramphenicol (table II)

Discussion

Residence in hospital for one week resulted in an increase in the fæcal carrier-rate from 17 to 38% for coagulase positive staphylococci and from 5 to 35% for serotype ac/- staphylococci Hospital infection with serotype ac/- was in all cases an infection with antibiotic cross resistant strains A comparable rise in the nasal carrier rate also occurred over the same period

Oeding and Austarheim (1954), in a study of the intestinal conten[illegible] of routine necropsy material reported the frequent occu[illegible]ce of staphylococci in patients who had been treated w[illegible]th antibiotics The predominant serological type in th[illegible]s study was the enterotoxin producing group abc or a[illegible] which appears to be the same as our serotype ac/

The frequency with wh[illegible] intestinal infection with serotype ac/- staphylococci is [illegible]equired in hospital seems to have a twofold significance First it may explain pseudomembranous enterocolitis and diarrhœa starting during the first eight days after partial gastrectomy (*Lancet* 1955b) Secondly it underlines the need to reconsider our ideas about the sources of staphylococcal infection with particular reference not only to the nasal carrier but also to the fæcal carrier This change in outlook regarding the sources of infection must inevitably have repercussions on our ideas about the method of transfer of infection and the means of preventing cross infection

It seems reasonable to suppose that the "weight" of organisms released to the environment by the fæcal carrier greatly exceeds that of organisms released by the nasal carrier, and this would explain the ease with which staphylococci can be recovered from the hospital air and dust It also raises the question of the transfer of staphylococci by the fæcal oral route in the same way as that which is believed to operate in bacillary dysentery and infantile gastro enteritis

The tracing of sources of infection in staphylococcal outbreaks is possible only by typing The value of phage typing has been established at the academic level This is time consuming and specialised work The method of typing in this investigation has the merit of being within the scope of the clinical pathologist The only special requirement is the preparation and issue of standard antisera

Summary

Analysis of staphylococci by serological typing and sensitivity testing has shown that the staphylococcus carrier state of the general community (new admissions to hospital) differed from that of a hospital community

The general carrier-rate was doubled as a result of hospitalisation

Nasal carriers of serotype ac/- increased fourfold (from 6 to 27%), while fæcal carriers increased sevenfold (from 5 to 35%)

In hospital practice the fæcal carrier of staphylococci, especially serotype ac/-, seems to play a more important part in communicating staphylococcal disease than has been realised

We thank Prof W J Tulloch for encouragement, Dr W Jamieson for clinical facilities, Mr H Lawrence, A I M L T, for technical assistance, and the Medical Research Council for an expenses grant to one of us (T S) for a technician.

FLEMMING KISSMEYER-NIELSEN *
M.D Aarhus

From the Institute of General Pathology and the Radium Centre for Jutland, University of Aarhus, Denmark

THE successful treatment of two cases of thrush œsophagitis with hydroxystilbamidine has been reported by Wolff et al (1955)

In vitro experiments (Stenderup 1955) have shown that even low concentrations of stilbamidine and pentamidine often prevent the growth of *Candida albicans* We have therefore tried pentamidine in the treatment of moniliasis and report here the results obtained in three cases All three patients had chronic malignant disorders, and it is well known that such patients are very susceptible to infection by *C albicans*

---

Course and treatment in case 1 each + represents a colony of C albicans

Case-reports

Case 1—A man, aged 57, was admitted to hospital on Sept 14 1954, with chronic myeloid leukæmia On Oct 2 he became febrile and complained of pain in his left flank below the left costal margin on breathing He had no rigors, cough, or dyspnœa, but produced a little yellowish sputum Auscultation of his lungs revealed signs of pneumonia, and radiography showed a homogeneous opacity in the upper lobe of his right lung

Treatment and Course—Treatment with penicillin, aureomycin (chlortetracycline), and penicillin with streptomycin successively was unsuccessful (see figure), the patient became worse and cyanosis and dyspnœa developed Repeated bacteriological studies of the patient's sputum failed to reveal any pathogenic bacteria but showed increasing numbers of colonies of *C albicans* until they were present in almost a pure growth Therefore a course of intramuscular pentamidine 200 mg daily was started on Oct 16 By mistake no pentamidine was given next day, but from Oct 18 daily injections were given The response not being satisfactory after the first few days' treatment, the dose was increased to 200 mg twelve hourly on Oct 21 This led to rapid clinical improvement, and four days later the patient's temperature had returned to normal Daily mycological study of the sputum showed that the number of colonies of *C albicans* decreased with the fall in temperature (see figure) Pentamidine was given for the last time on Oct 28, and on Nov. 3 no fungi could be isolated from the sputum

In vitro studies of the patient's strain of *C albicans* showed that pentamidine in a concentration of 1/512 mg per ml of substrate partially inhibited growth, and 1 128 mg per ml of substrate completely suppressed macroscopic growth (for technique see Stenderup 1955)

Case 2—A man, aged 25, was admitted to hospital on May 27, 1955, with Hodgkin's disease of three years' duration During this period his condition had become progressively worse During his stay in hospital he complained of feeling as if he had a lump in his throat and of retrosternal pain in swallowing Inspection of the throat revealed a white membrane covering the pillars of the fauces and the posterior wall of the nasopharynx, from which *C albicans* was isolated Radiography of the œsophagus showed no abnormalities

Treatment and Course—The symptoms were thought to be due to monilial infection extending into the œsophagus, so treatment with intramuscular pentamidine 200 mg daily was started on July 9 Œsophagoscopy a few days later showed that the hypopharynx and the upper part of the œsophagus were covered with a dense white fungous membrane, and the underlying mucosa was red and œdematous and tended to bleed Since the mucosa seemed to be very friable, the œsophagoscope was introduced for a distance of only 20 cm Culture of a biopsy sample yielded a heavy pure growth of *C albicans* During pentamidine therapy the discomfort of the throat rapidly subsided, and after twelve days' treatment both the faucial coatings and discomfort had disappeared completely Pentamidine was therefore discontinued, and œsophagoscopy showed that the entire œsophagus was almost normal The mucosa was perhaps slightly swollen, and a few pinhead sized plaques persisted from which *C albicans* could still be isolated

Case 3—A man, aged 35, had had Hodgkin's disease from the age of 8 years and had been given large doses of X rays to enlarged lymph nodes of the head and neck After a course of irradiation in 1953 he complained of dryness and burning pain in his mouth His oral, lingual, and pharyngeal mucosa became atrophic, with a tendency to the formation of crusts, purulent secretion, and hæmorrhages These changes persisted and caused him great discomfort, and he was admitted to hospital on Sept 9, 1955

On admission he was critically ill, very weak, and anæmic He complained of the aforesaid symptoms in his mouth and throat and of white coatings in his mouth, which had lasted a couple of months and caused him considerable discomfort He had difficulty in swallowing and thought he had lost weight

Examination revealed that his entire oral mucosa, his tongue, the pillars of his fauces, and his pharyngeal wall were completely covered with a thick yellowish membrane, and his breath was offensive Œsophagoscopy showed that this membrane was present all over the œsophageal mucosa right down to the cardia Culture of the membrane grew *C albicans*, *C pseudotropicalis*, and *C krusei* In vitro studies showed that pentamidine in a concentration of 1/512 mg per ml of substrate suppressed the growth of all three species

Treatment and Course—From Sept 8 intramuscular pentamidine 200 mg twelve hourly was given After a week's treatment only scattered plaques remained on the oral and pharyngeal mucosa Œsophagoscopy on Sept 15 showed that the œsophagus was still covered by a membrane, which, however, was less adherent, the underlying mucosa was red and inflamed and tended to bleed Pentamidine therapy was therefore continued The general condition of the patient deteriorated, and the symptoms due to the state of the mucosa did not subside, even though the monilial infection decreased On the morning of Sept 21 the patient was found unconscious in bed, and he died a few hours later

Necropsy revealed extensive granulomatous change in the spleen, liver, and lymph nodes, probably due to atypical Hodgkin's disease No membranes on the hypopharynx and œsophagus were visible to the naked eye The œsophageal mucosa was red and atrophic, and microscopy revealed chronic œsophagitis Scattered fragments of mycelium and candida spores were still present

The objective improvement of the moniliasis, despite the deterioration of the general health and the poor condition of the oral and pharyngeal mucosa, seems remarkable and must be ascribed to the treatment with pentamidine

Discussion

In view of the good results obtained with pentamidine in these cases and with hydroxystilbamidine in the cases of thrush œsophagitis reported by Wolff et al (1955) the diamidines must be assumed to be useful in the treatment of moniliasis

The effects were not obtained in the present cases so quickly as in those treated by Wolff et al This may be due to the fact that these workers administered the drug intravenously Hydroxystilbamidine may also exert a greater effect than pentamidine does on *C albicans*, but it is scarcely possible to be definite about this, because different strains of *C albicans* may differ in sensitivity even to the same diamidine

Summary

Three cases of moniliasis were successfully treated with pentamidine

THE EFFECT OF 3:5:3′-TRIBROMO-DL-THYRONINE IN MYXŒDEMA

Nigel Compston
M.A., M.D. Camb., M.R.C.P.
ASSISTANT PHYSICIAN, ROYAL FREE AND HAMPSTEAD GENERAL HOSPITALS

Rosalind Pitt-Rivers
Ph.D. Lond., F.R.S.
MEMBER OF SCIENTIFIC STAFF, NATIONAL INSTITUTE FOR MEDICAL RESEARCH, MILL HILL, LONDON

It has been shown (Mussett and Pitt-Rivers 1954) that DL-tribromothyronine possesses considerable activity in preventing thiouracil-induced goitre in rats. In these experiments it was found to be nearly half as active as DL-thyroxine, while DL-tetrabromothyronine only had about 1/200 of the activity of thyroxine. Tetrabromothyronine has previously been shown to have some thyroxine-like activity in man (Lerman and Harington 1949). It is possible, however, in view of the 100-fold difference in the goitre-preventing activity of tribromothyronine and tetrabromothyronine, that the response in human myxœdema obtained by Lerman and Harington may have been, in part, due to contamination of the tetrabromo compound with tribromothyronine. In the present study the tribromothyronine used was demonstrated to be chromatographically free from the tetrabromo compound.

This study was not undertaken in anticipation of any therapeutic advantage of tribromothyronine over other thyroxine analogues but because the demonstration of high thyroxine-like activity of non-iodine-containing analogues of thyroxine in man must cause a reorientation of fundamental views of thyroid physiology.

Two myxœdematous patients have now been treated with tribromothyronine.

Case-reports

Case 1.—A man, aged 68, was first seen as an outpatient on Dec. 17, 1954. He complained of swelling of the hands and feet and of "big bladders" around the eyes for three weeks. He admitted to excessive lethargy, rising weight, constipation, coldness and pins and needles in the legs, "thickness" of the voice, and increasing deafness for a few months. The history was amplified by his wife, who stated that for two years, since giving up his work as a butcher, he had become progressively more slow in all his activities. He had tended to fall asleep at the slightest opportunity and spent his day huddled over the fire.

Examination.—When admitted to the Royal Free Hospital on Dec. 30, his appearance was typical of myxœdema. His responses were slow but there was no suggestion of psychosis. His voice was very low pitched and rasping. His features were coarse, his skin thickened and dry. He had supraclavicular pads. His scalp hair was normal but his eyebrows were deficient. He had pitting œdema of the hands, feet, and ankles. His mucosæ were normal. No thyroid tissue was palpable. His pulse-rate was 64, pulse regular, blood-pressure 180/105 mm. Hg; there were no signs of congestive heart failure, and no abnormality was found on examination of the heart. The lungs, abdomen, and central nervous system were normal.

On clinical grounds a diagnosis of primary myxœdema was made.

Investigations

The basal metabolic rate (B.M.R.) was −34% (Aub Du Bois) and the blood-cholesterol level 300 mg. per 100 ml. The uptake of radioactive iodine was subnormal, only 9% of the dose being taken up in the neck at twenty-four hours. Radiography of the chest showed cardiac enlargement, with normal lung fields. Hæmoglobin 13·3 g. per 100 ml. (90%); no morphological abnormality of blood-cells; generalised hypoplasia in bone-marrow. Electrocardiography showed sinus rhythm, normal voltage, Q R S 0·13 sec., and left bundle-branch block.

Treatment and Progress

Treatment with tribromothyronine was begun on Jan. 13, 1955. In view of the patient's age and electrocardiographic evidence of degenerative heart disease very small doses (100 µg.) of intramuscular tribromothyronine were used initially and gradually increased to 1000 µg. This dosage was also indicated because the degree of thyroxine-like activity that tribromothyronine might prove to have in man was unknown.

Progress was judged clinically, by B.M.R., by blood-cholesterol levels, by weight changes, and by fluid balance. The dosage of tribromothyronine and other data are recorded in fig. 1.

Soon after the start of treatment the patient stated that he felt better and he became increasingly alert and active. His voice, by the end of the period of study, was normal, and hearing had improved. His B.M.R. had risen from −34% to 0%, his blood-cholesterol level had fallen from 300 mg. to 144 mg. per 100 ml., and his weight from 159½ lb. to 138 lb. There was a period from five to ten days after the start of treatment when his weight increased temporarily in association with increasing œdema of the legs.

Fig. 1 shows that about four weeks after the start of treatment the character of the fluid-balance chart alters. At that time, and for three weeks subsequently, the patient's fluid intake was equalled by his urinary output. Although dietary fluid and insensible fluid loss have not been included in the fluid balance, probably during this period he was in a negative fluid balance owing to a diuresis.

Treatment with tribromothyronine was discontinued on March 30 and he has since then been maintained on thyroid gr. 4 daily. During a further three months' observation he has remained clinically normal, his weight has been steady, and his B.M.R. has remained in the normal range.

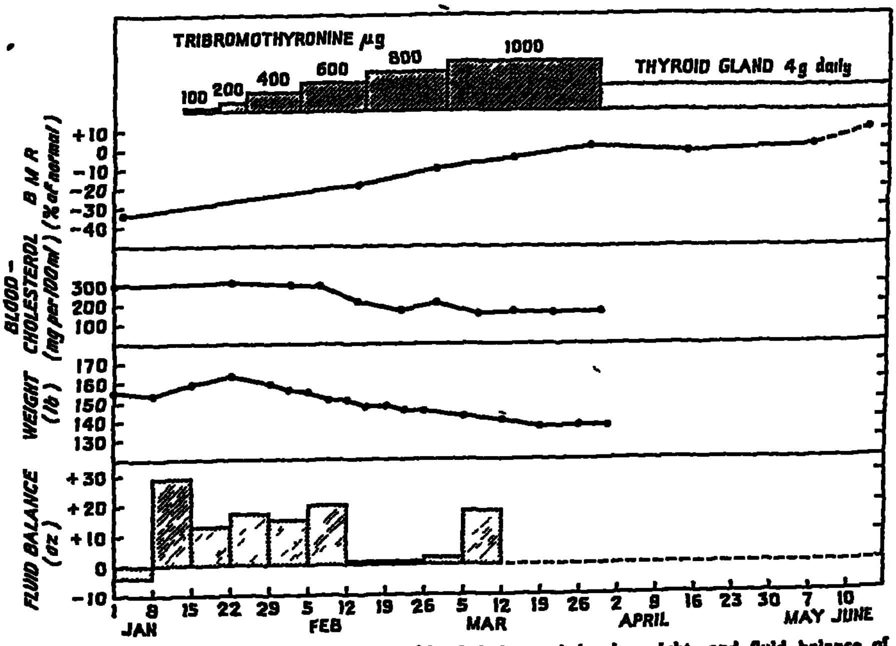

Fig. 1—Dosage of tribromothyronine, B.M.R., blood-cholesterol level, weight, and fluid balance of case 1. Intake and output of fluid are expressed as the average daily difference during each week of observation.

Case 2.—A man, aged 65, was admitted to the Hampstead General Hospital as an emergency on Jan. 16, 1955. On the

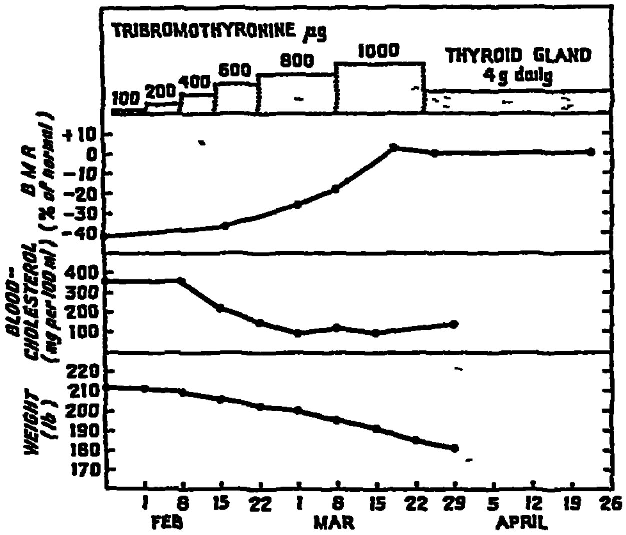

Fig 2—Dosage of tribromothyronine B.M R blood-cholesterol level and weight in case 2.

morning of admission he had suddenly become confused and lost consciousness for an hour. On admission he had dysphasia in association with mild pyramidal tract signs on the right side. He also appeared myxœdematous. At first it was impossible to obtain a history, but after a few days and with the help of his wife the following history was obtained. For some years he had been becoming increasingly lethargic both physically and mentally. He had gained much weight. His eyes had been puffy for a year, and his voice gruff for many years. He had recently felt the cold excessively.

Examination

His scalp hair was coarse and sparse and his eyebrows were thin. His voice was typically myxœdematous. He was deaf and had been so since middle life, but his deafness had increased in the last few years. There was no clinical evidence of anæmia. No thyroid tissue was palpable. The pulse rate was 66 and the blood-pressure 140/100 mm Hg. The apex beat could not be localised, the heart sounds were distant, but no other abnormality was detected. The chest and abdomen were normal. There was pitting œdema of the legs.

On clinical grounds a diagnosis of primary myxœdema was made.

Investigations

The B.M.R. was −40% (Aub Du Bois), and the blood-cholesterol level 356 mg per 100 ml. There was no uptake of radioactive iodine in the neck in twenty-four hours. Radiography of the chest showed moderate cardiac enlargement. Electrocardiography showed sinus bradycardia (54 per min.), low-voltage Q R S complexes, flattened P waves in all leads, and flattened or inverted T waves in all leads. Hb 87%, packed-cell volume 41 mm., generalised hypoplasia of bone marrow with no morphological abnormality.

Treatment and Progress

Treatment with intramuscular tribromothyronine 100 µg daily was begun on Jan 27 and the dose was gradually increased to 1000 µg daily.

Progress was assessed clinically, by B.M.R., by blood-cholesterol levels, and by weight changes (fig 2). There was a temporary increase in œdema for the two weeks following the start of the treatment. Under treatment with tribromothyronine this patient's B.M.R. rose from −41% (Aub-Du Bois) to −2%, his serum cholesterol level fell from 356 to about 100 mg per 100 ml, and his weight decreased from 212½ lb to 185 lb.

On March 24 treatment with tribromothyronine was stopped and the patient was given tab thyroid *B P* gr 4 daily. A month later the B.M.R. was still normal and his clinical state satisfactory. Further observations were impossible, because this patient died after a road accident.

Comment

From these results it is apparent that DL tribromothyronine in a dose of 1 mg daily can restore normal metabolism in myxœdema. In the two present cases normality was maintained, after treatment with tribromothyronine had been stopped, with thyroid gr 4 daily, but owing to the death of the second patient the follow-up was not long enough to establish that dosage as being the permanent requirement. If this dosage is indeed equivalent to 1 mg of tribromothyronine it appears that 1 mg of DL-tribromothyronine is equivalent to 0·4 mg of L thyroxine (the quantity contained in gr 4 of desiccated thyroid).

One may reasonably assume from previous published evidence that the D-isomer in DL-tribromothyronine is virtually inactive in human myxœdema. It therefore appears that tribromothyronine has only slightly less activity than thyroxine itself, since 1 mg of the DL-compound (containing 500 µg of the L isomer) had activity equivalent to gr 4 of desiccated thyroid.

Conclusions

Two patients with primary myxœdema were treated with DL-tribromothyronine.

Both patients responded fully to a daily dose of 1 mg. of this compound.

Tribromothyronine appears to have only slightly less thyroid-like activity than has thyroxine.

SICKLE-CELL/HÆMOGLOBIN-D DISEASE

IN A MULATTO GIRL

J W STEWART
M B Lond
SENIOR LECTURER IN HÆMATOLOGY

J E MACIVER
M B Camb
LECTURER IN HÆMATOLOGY

BLAND SUTTON INSTITUTE OF PATHOLOGY, MIDDLESEX HOSPITAL MEDICAL SCHOOL, LONDON

SICKLE-CELL anæmia is a well known congenital and familial hæmolytic anæmia, first described by Herrick (1910) in a West Indian Negro from Granada. For many years it was considered to be peculiar to Negroes but it occurs also among peoples in whom no negroid ancestry is apparent (Cooley and Lee 1929, Lehmann and Cutbush 1952, Choremis et al 1953).

It owes its name to the peculiar shape assumed by the erythrocytes under reduced oxygen tension, when the hæmoglobin inside the cells does not remain in solution (Perutz et al 1951) and the resultant "crystallisation" or "gelling" is responsible for the characteristic deformity.

The hæmoglobin inside the sickle cells differs from normal hæmoglobin both in its solubility under reduced oxygen tension (Singer and Singer 1953) and electrophoretically (Pauling et al 1949, Wells and Itano 1951). This abnormal hæmoglobin is called hæmoglobin S. The terminology used here for the various types of hæmoglobin is that recommended by the National Institutes of Health (1953).

Neel (1947, 1949, 1951) has shown that hæmoglobin S is inherited as a mendelian dominant, and he has postulated heterozygous and homozygous genes to explain symptomless sickle-cell trait and the true sickle cell anæmia. If an individual receives the hæmoglobin-S gene from one parent only (the heterozygous state), he

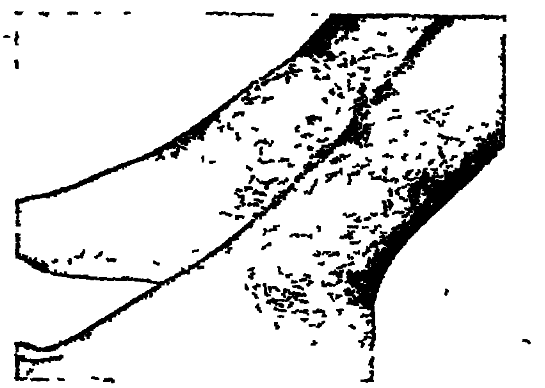

Fig. 1—Ulceration of patient's ankles.

will have the harmless sickle-cell trait, whereas if a hæmoglobin-S gene is received from each parent (the homozygous state), then the individual will suffer from sickle cell anæmia. Sickle cell trait is very much more common than sickle-cell anæmia and occurs in 5–40% of Negroes (Jelliffe et al. 1954).

Neel (1951) recognised that there were occasional exceptions to his hypothesis—for example, cases of sickle cell anæmia in which the erythrocytes of only one parent sickled. Further study of these exceptional cases has disclosed two other abnormal inherited hæmoglobins (C and D) and shown that the inheritance of hæmoglobin S from one parent and either hæmoglobin C (Itano and Neel 1950, Kaplan et al. 1951, 1953, Neel et al. 1953) or hæmoglobin D (Itano 1951, Dacie 1954) from the other produces a condition clinically very similar to sickle cell anæmia.

We report here a case of sickle cell/hæmoglobin-D disease.

Case-report

A single woman, aged 32, attended surgical outpatients with ulceration of her ankles (fig. 1). She was a mulatto with an English mother and was also said to have sickle cell anæmia.

Examination of her blood showed anæmia (Hb 60% = 8·7 g. per 100 ml.). *Her erythrocytes sickled readily into the long filamentous forms typical of sickle cell anæmia (fig. 2).* Fresh wet marrow flecks showed mycelia-like filaments (fig. 3) similar to those described by Vandepitte and Louis (1953). The electrophoretic pattern of her hæmoglobin was indistinguishable from that seen in sickle cell anæmia.

Family History

Thus both clinically and hæmatologically the case appeared to be one of true sickle-cell anæmia in a girl of mixed African and English descent (Stewart and MacIver 1954), but her family history (fig. 4) was most unusual. Her deceased father was a West African Negro, so we assume that he was the source of the patient's hæmoglobin S gene. Her mother was English, and had no known foreign antecedents. Her blood-count was normal and her erythrocytes did not sickle. The patient's two brothers also had normal blood counts, and their erythrocytes did not sickle. The sickle test was made by three different methods—plain wet sealed, 2% sodium metabisulphite, and 2% sodium dithionite—and at least six preparations were made for each member of the family. Only in the patient was the sickle test positive.

Filter-paper electrophoresis of hæmoglobin solutions from all surviving members of the family was done with the vertical tank of Flynn and de Mayo (1951) and a barbitone buffer pH 8·6 at 220 V and 6 mA for 20 hours. The results are shown in fig. 5, including normal and abnormal controls run at the same time. It will be seen that the mother and the brother A have an abnormal band of hæmoglobin of reduced mobility compared with normal hæmoglobin. Density scanning of the strips indicates that about half of each type of hæmoglobin is present in the samples. The patient's hæmoglobin gave a single abnormal band of similar mobility to the abnormal hæmoglobin of her mother and her brother A. In the other brother a normal hæmoglobin pattern was found.

The patient's hæmoglobin was of the same electrophoretic mobility as hæmoglobin S. This can be interpreted as showing that her hæmoglobin is either of this type alone or mixed with hæmoglobin D, which is the only type so far known to be of the same electrophoretic mobility as hæmoglobin S. The electrophoretic pattern in the mother and brother A also shows a band in the S and D position, but their erythrocytes do not sickle.

● Patient: sickle test positive

▨ Not examined (dead)

◎ Sickle test negative: electrophoresis shows abnormal hæmoglobin

○ Sickle test negative: electrophoresis shows normal hæmoglobin

Fig. 4—Patient's family tree (see text).

Any erythrocytes containing 50% of hæmoglobin S will sickle readily by any of the methods which we used. Therefore this abnormal hæmoglobin must be hæmoglobin D.

We are indebted to Dr. J. C. White, of the Postgraduate Medical School of London, for the following report on the solubility of a hæmoglobin sample from the patient's mother:

“The solubility of the reduced hæmoglobin was determined in pH 6·7 phosphate buffer, ionic strength 4·75. In a system containing 10 g. per litre of protein, the solubility was 5·7 g. per litre. The hæmoglobin-D trait which I examined (Dacie 1954) gave a result of 6·0 g. per litre. These values are below the normal mean, though in the lower normal range, but are far higher than for sickle cell trait under the same conditions.

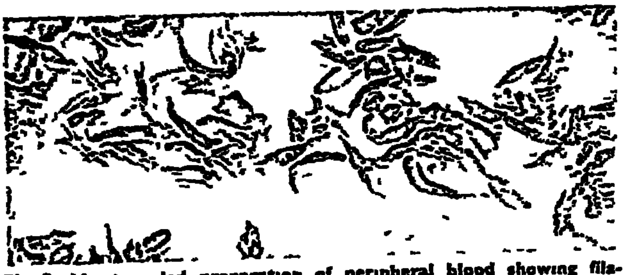

Fig. 2—Moist sealed preparation of peripheral blood showing filamentous sickling (×470).

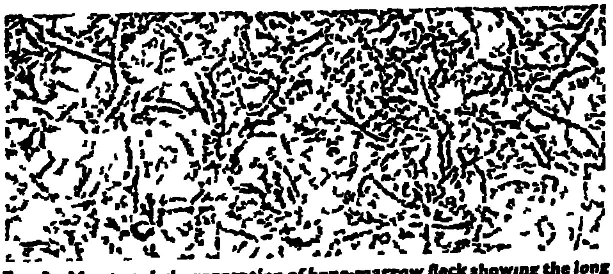

Fig. 3—Moist sealed preparation of bone-marrow fleck showing the long mycelia-like structures (×470).

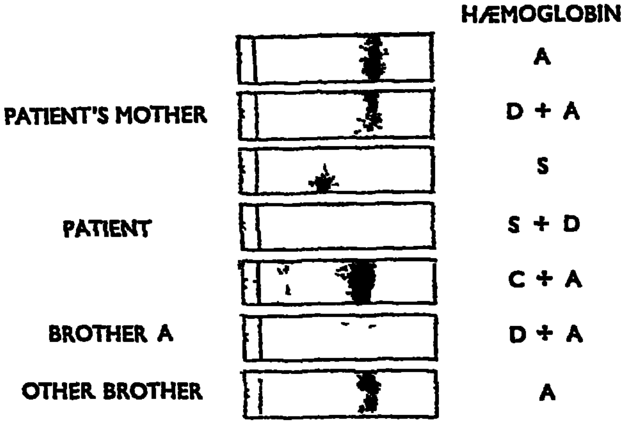

Fig 5—Filter-paper electrophoresis of different hæmoglobins run in parallel

(1–3 g per litre) Together with the electrophoretic result of a normal hæmoglobin fraction and a fraction with the mobility of hæmoglobin S this fully confirms that the patient's mother has hæmoglobin-D trait "

Discussion

Sickle-cell anæmia is usually due to a homozygous gene for hæmoglobin S—in other words, both parents of a patient with sickle cell anæmia usually possess this abnormal gene at least in the heterozygous state (Neel 1947, 1949, 1951) In the present case we must assume the inheritance of the gene for sickling from the father, both because he was a West African Negro and because the mother did not have hæmoglobin S Since there was no normal hæmoglobin (hæmoglobin A) in the patient's erythrocytes, the mother must have passed on the gene for the only abnormal hæmoglobin which she possessed—hæmoglobin D Therefore the hæmoglobin in the patient's erythrocytes must be a mixture of hæmoglobins S and D The electrophoretic pattern of her hæmoglobin is compatible with this hypothesis

We have previously discussed the criteria to be fulfilled before sickle cell anæmia can be definitely diagnosed (Stewart and MacIver 1954) The patient satisfied all these criteria both hæmatologically and clinically Subsequently she was readmitted in extremis, and necropsy revealed pyelonephritis The changes in the other organs were as described for sickle-cell anæmia (Wintrobe 1951) In particular the spleen (fig 6) was very shrunken and measured only $1^3/_4 \times {}^1/_4 \times {}^3/_4$ in

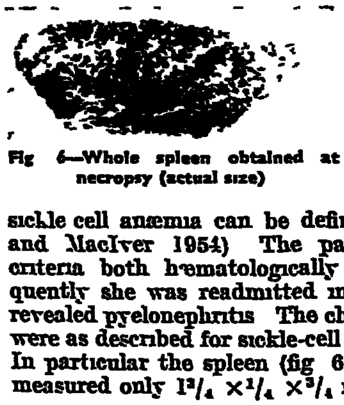

Fig 6—Whole spleen obtained at necropsy (actual size)

It is therefore evident that electrophoretic analysis of the hæmoglobin types present both in patients and their parents is necessary before a diagnosis of true sickle-cell anæmia can be made

Summary

A woman with sickle cell/hæmoglobin-D disease inherited the abnormal hæmoglobin D from her English mother The father, a West African Negro, was dead and is assumed to have supplied the gene for the hæmoglobin S One of the patient's brothers had also inherited the abnormal hæmoglobin D

This case emphasises the importance of investigating obscure hæmolytic anæmias for the presence of abnormal hæmoglobins

We wish to thank Prof A. Kekwick, under whose care the patient was admitted, for allowing us access to the case and for permission to publish, Miss H Silberman for the electrophoretic studies, and Dr P Harrison Hall for the post-mortem report

Preliminary Communication

WILSON'S DISEASE

NEW ORAL THERAPY

In patients with hepatolenticular degeneration (H L D) there is an accumulation of excess copper in the tissues and an abnormally high excretion of copper in the urine The extensive literature on this subject has been reviewed and discussed by Cartwright et al [1] It has been shown by Cummings [2] and many subsequent workers that the excess copper in these patients can be mobilised by the parenteral administration of dimercaprol (BAL), intravenous 'Versene' and intravenous amino-acids are also effective,[1 3] and cortisone and high-protein diets have been found of value as adjuvant therapy [4] Dimercaprol has proved the most effective of these forms of treatment and if given over long periods causes distinct clinical improvement, particularly in patients with the more chronic forms of the disease [5] However, repeated injections of dimercaprol are extremely painful and are often associated with undesirable side-reactions, so not all patients can benefit from this form of treatment

The object of the present investigation has been to find a non-toxic compound that could be given by mouth and would promote the excretion of copper The activity of dimercaprol is due to the presence of two thiol groups in the molecule, these compete with the thiol groups in the tissues for the excess copper which is present, and the dimercaprol copper complex is then excreted in the urine Some earlier work [6] has suggested that penicillamine (β, β dimethyl-cysteine) is excreted in the urine after parenteral administration of penicillin Since this compound is excreted in the reduced (–SH) state after being formed in the body it appeared possible that it would also remain reduced when given by mouth and that the thiol group might prove active in the removal of copper

So far two healthy people have each received a single dose, and two patients with H L D have received four and three trial doses, of penicillamine The copper excretion has been estimated and, in the patients, compared with that produced by a dose of dimercaprol containing an approximately equimolar amount of sulphur These preliminary tests suggest that dimethyl cysteine is as active as dimercaprol in promoting the removal of copper from the body Dimethyl cysteine hydrochloride was given as three daily doses each of 300 mg ; the drug was given about half an hour before meals in order to avoid its chelating with copper present in the diet In these short term experiments no toxic reactions were observed

A detailed report of this work is in course of preparation, and the possible use of this form of treatment for long term maintenance of patients with H L D is discussed with reference to possible chronic toxicity and precautions which should be taken in undertaking a long-term study Reference is also made to the treatment of other heavy metal poisonings with penicillamine

This work was done at the Thorndike Memorial Laboratory and the 2nd and 4th Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston, Massachusetts I am most grateful to Dr C S Davidson for his advice and encouragement, to Dr D Denny Brown for allowing me to study two of his patients, and to Dr Augustus Gibson, of Merck & Co, Rahway, N J, and to Prof John Sheehan, of the Massachusetts Institute of Technology, for supplies of penicillamine

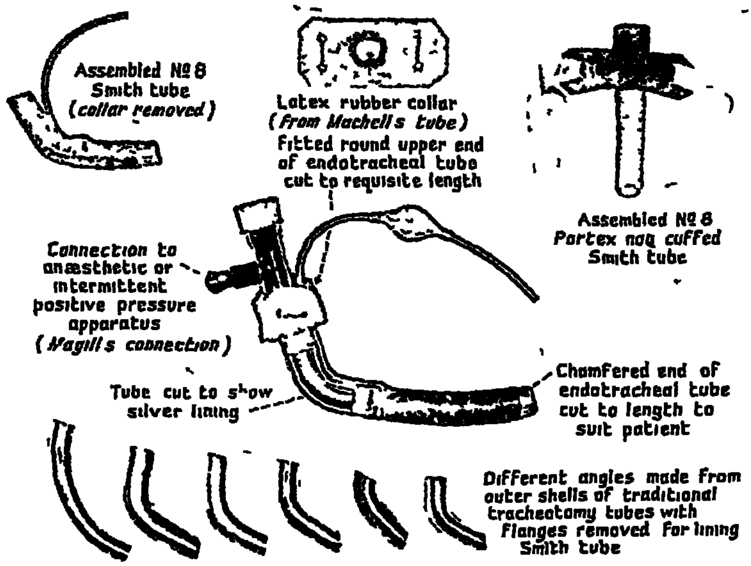
New Inventions

A TRACHEOTOMY TUBE FOR USE IN ACUTE POLIOMYELITIS

THE maintenance of a tracheotomy tube during emergencies may lead to many difficulties, especially before the tracheostomy tract has properly formed

Fixation —*The normal movements of patient and attach*ments with intermittent positive pressure inflation, routine posturing, and drainage may easily displace an ordinary cut down anæsthetic endotracheal tube which may cause surgical emphysema and traumatic pneumothorax If a long stemmed tube is used, a bronchus may become blocked, causing retention of carbon dioxide and respiratory embarrassment



Kinking —Complete occlusion of the lumen of a tracheotomy tube may be more obvious, but no more lethal, than partial occlusion, which may often be produced in anæsthetic tubes, even armoured tubes may close partially in the anteroposterior diameter This may be detected before use by trying to withdraw a suction catheter (which has previously just passed easily), if it is gripped when the tube is bent, the latter should be discarded

Tracheal Ulceration —In debilitated patients direct pressure of an inflated cuff may cause ischæmia *of the tracheal mucosa*, and a tube without a rigid angle may rub the posterior tracheal wall owing to its relative inflexibility

Angulated rubber tracheotomy tubes (Morrant Baker) may be the best of those tubes readily available for use with intermittent positive-pressure inflation, and, carefully selected to suit the patient, are unlikely to kink However, the short intratracheal portion of these tubes, especially in the smaller sizes, does not allow easy fixation of slip-on cuffs, which in any case are clumsy and unsuitable for prolonged use Moreover the fixation of connections to the flush external flange is difficult, especially when surgical dressings are present, as in the early postoperative stages Some rubber tubes are of inconstant diameter, having an irregular inner wall which prevents the easy passage of a suction catheter

In the Portsmouth Poliomyelitis Centre a tracheotomy tube has been improvised by several members of the staff jointly which appears to have none of the aforementioned disadvantages and many additional advantages None of us accepts full responsibility or claims any originality for this tube, so we call it the Smith tube after the first patient in whom it served as a reliable non-traumatic airway during many days of intermittent positive pressure inflation

The Smith tube is essentially a suitably selected and cut-down anæsthetic endotracheal tube into which is slid, to make a tight fit, a similarly selected silver lining, which is the outer shell of a standard silver tracheotomy tube from which the external flange has been removed In the accompanying illustration the wall has been cut away from a Smith tube to *show the lining* A latex rubber collar is attached

The advantages of the Smith tube are as follows

(1) The fixed curve and attached collar make fixation easy and reliable

(2) The tube *cannot* be *compressed* or occluded in any diameter

(3) A smooth and regular inner wall allows the passage of the largest possible suction catheter at all times

(4) The fixed curve ensures that there is no pressure on the posterior tracheal wall

(5) Variable intratracheal and extratracheal lengths can be selected (above and below angle) to suit the portion of trachea available above the carina, and to make easy connection with anæsthetic or intermittent positive pressure apparatus

(6) The Smith tube can be made of different sizes, lengths, shapes, and *lumina and cuffed or uncuffed from ready to hand* materials at low cost

Reviews of Books

Biochemistry and the Central Nervous System

Henry McIlwain, PH D D SC, professor of biochemistry in the University of London at the Institute of Psychiatry
London J & A Churchill 1955 Pp 240 40*s*

TODAY emphasis in biochemical thought is on the nature of dynamic processes rather than on mere cataloguing of tissue constituents which was the preoccupation of earlier workers, and Professor McIlwain's book gives a striking illustration of this trend He discusses most of the important topics of current interest in cellular metabolism, and skilfully develops the basic ideas in relation to the special case of nervous tissue It is remarkable how much data he has assembled to demonstrate the actual behaviour of neural material without having to extrapolate from other organs Professor McIlwain's own work on the effect of electrical stimulation on the "in-vitro" metabolism of cerebral tissues receives due consideration, but is not overemphasised, and in this and other respects his presentation is extremely well balanced

After a brief historical introduction, there is a chapter on the study of cerebral metabolism in the intact animal, which summarises work on the oxygen and glucose consumption of the organ under various conditions, based on analyses of afferent and efferent blood Next comes a discussion of the chemical composition of the brain with particular reference to the constituents, such as creatine phosphate, whose concentration varies with cerebral activity The middle five chapters of the book are concerned with a straightforward account of intermediary metabolism The chapter on lipids reviews recent work on the fractionation of the cerebral lipids, and on turnover studies of these materials There follows a fascinating chapter on the changes in the make up of the brain through development before and after birth An account of chemical transmitters and the in vitro effects of depressant and excitatory drugs on brain metabolism leads to a final chapter on the speed of chemical changes in the brain, which includes some intriguing calculations made by the author from various published data on this subject

Written in a style that is unexciting but usually perfectly clear, the book will attract workers in neurology and psychiatry who want to keep up with the results of modern biochemical research, and biochemists and neurochemists will find that it gives a useful conspectus of familiar ideas

Blood Supply and Anatomy of the Upper Abdominal Organs

Nicholas A Michels, M A, D SC, professor of anatomy, Jefferson Medical College, Philadelphia Philadelphia J B Lippincott London Pitman Medical Publishing Co 1955 Pp 581 £8

THIS book is mainly concerned with the variations of the arterial supply to those organs which lie above the mesentery of the transverse colon

In part, it is a descriptive atlas of 165 figures, most of which illustrate these variations The essential features of the figures dealing with the gall bladder and liver are summarised in six plates Other figures show variations of the extra hepatic bile ducts, and the remainder illustrate the gross anatomy of the intrahepatic biliary, arterial, and venous systems

The atlas is preceded by a text which includes descriptions of the arterial variations, based on some 500 dissections by the author Accounts are also included of the blood supply of the œsophagus and the gut distal to the duodenum These are derived from the observations of others, but supplemented by Professor Michels's own experience There are discussions on collateral circulations in the upper abdomen and on the circulations within the liver and the spleen The text ranges widely over other material, and includes a chapter on the variations of the biliary system A vast composite chapter deals with the structural features, embryology, and anomalies of the upper abdominal organs Here the main emphasis is on the biliary apparatus, and the structure of the lower end of the common bile duct is dealt with in detail There are sections in this chapter on gall stones, on the comparative anatomy of the bile ducts, on the liver in relation to divination, and on the first cholecystectomy performed in America There is a bibliography of some 850 references, many more given in the text do not appear in it

The emphasis throughout is on the applied anatomy, and this is essentially a book intended for those who operate on the upper abdominal organs The terminology is clear, and the figures are admirably designed and executed, few surgeons could fail to learn something of value by looking through the atlas The text is in general clearly written and comprehensive though there are some repetitions and irrelevancies The general production is good, the price is frightening

Techniques in Blood Grouping

Ivor Dunsford, senior scientific officer, Regional Blood Transfusion centre, Sheffield, C Christopher Bowley, M B, M R C O G, director of the centre Edinburgh Oliver & Boyd 1955 Pp 250 21*s*

PRIMARILY a practical guide for use in the laboratory, this book concentrates on providing, in full detail, "a comprehensive set of techniques needed by those engaged in blood grouping work"

The first of the three sections explains briefly the theoretical and factual bases on which the practical schemes rest, and even in this section, the practical standpoint predominates For instance, in addition to dealing with the nature of immune iso antibodies and factors affecting blood group reactions, the authors have chapters on apparatus, causes of error, and the provision of antisera There is an interesting brief outline of basic and advanced courses for hospital laboratory workers

The second section gives really full details of 80 different techniques, beginning very properly with the cleaning of dirty glassware and ending with the identification of mixed antibodies In between every technique likely to be needed is thoroughly described the basic grouping techniques, the preparation of sera for diagnostic use, the differentiation of the sub groups of A (with a useful table), and more complex matters like rhesus genotyping Techniques for difficult situations—compatibility tests for children under 6 months, compatibility tests when time presses, and the investigation of cases of hæmolytic anæmia—are presented with commendable briefness The rare blood groups are all dealt with—but with a sense of proportion The rare blood groups also find a place in the third section which is a useful glossary

The book has a wire binding that enables it to lie flat wherever it is opened

This book will be welcomed with relief by all those who have to cope with the practical side of blood-transfusion work, but who have only the haziest ideas about the calculation of gene frequencies The price will enable every worker to have his own copy

Introduction to Hepatic Surgery

Henry Gans, M D, surgical resident, Cincinnati, Ohio New York Elsevier London Cleaver Hume 1955 Pp 265 70*s*

For his study of the anatomy of the Glissonian and the hepatic vein systems, Dr Gans cast the vessels in plastic material by injecting post-mortem specimens These casts have indicated a fairly constant lobe system within the liver which does not entirely correspond with the external appearances of the organ, some fine photographic reproductions illustrate this point, which is of importance to a surgeon contemplating partial hepatectomy Because of the anatomical detail and the technological style in which it is written, this book is more for reference than for reading Surgery is dealt with in general terms, physiology is not considered

Fractures of the Facial Skeleton

N L Rowe, M R C S, F D S R C S, and H C Killey, M R C S, F D S R C S, consultants in oral surgery, plastic and maxillofacial surgery unit, Rooksdown House, Basingstoke Edinburgh E & S Livingstone 1955 Pp 923 £6

THE two principal authors of this imposing textbook are primarily dental surgeons, and they have been assisted by two anæsthetists, four plastic surgeons, an ophthalmologist, and an oral surgeon This team has produced a splendid volume that covers virtually every aspect of maxillofacial injuries—a difficult and complex subject

Many clinical problems are fully explained and illustrated, including gunshot wounds, head injuries, secondary bone grafts, and soft tissue lacerations, and the technical matters discussed include the construction of metal cap splints and the various methods of interdental wiring There is an admirably terse chapter by Dr G J Romanes on ophthalmic injuries, though in face of this contribution it is a pity to find support elsewhere for the fallacy that loss of periorbital fat causes "an alteration of the pupillary level and a complaint of diplopia" Best of all, there is a fascinating chapter on the diagnosis and treatment of residual traumatic deformities by Sir Harold Gillies

An encyclopædic book is liable to lack balance, and some of this work's copiousness is due to material which might well be compressed or omitted The historical chapter runs to 50 pages, there is a long section on metallurgy and electrolytic phenomena, the chapter on radiography and radiology occupies 46 pages, and there are over 40 line drawings illustrating how to insert and tie skin sutures

Nevertheless, this book is clear, persuasive, and comprehensive, and it deserves to enjoy a special position in the maxillofacial literature of English-speaking countries

Medical Treatment of Mental Disease

The Toxic and Organic Basis of Psychiatry DANIEL J MCCARTHY, M D, LL D, consulting neurologist, Philadelphia General and Norristown State Hospitals, KENNETH M CORRIN, M D, neuropsychiatrist, Wilmington General Hospital Philadelphia J B Lippincott London Pitman Medical Publishing Co 1955 Pp 653 96s

LAUDABLY eager to remind family doctors and young psychiatrists that "there is much more to psychiatry than the purely psychological aspect," the authors go to the other extreme They assert, without evidence, that all, or almost all, mental disorder is a matter of disordered chemical and physiological processes

They leave aside not only the dynamic or psycho analytical psychopathology so prominent in most American textbooks of psychiatry, but also the findings of applied psychology, and they are evidently unaware of their own psychological assumptions There is certainly a need for a well informed American textbook that has not a strong psycho analytical bias, but this book does not supply the need

A Classification for Medical and Veterinary Libraries

2nd ed CYRIL C BARNARD, B A, F L A, F I L, librarian, London School of Hygiene and Tropical Medicine London H K Lewis 1955 Pp 279 £4 4s

THE late Sir John MacAlister once said "You can't classify a medical library without doing more harm than good", and many of those who have had to struggle with some of the schemes for keeping books in order would agree with him In a large library the choice of a classification is one of the librarian's biggest problems, and unfortunately some of the ingenious methods that have been devised are too complicated for everyday use Universal schemes suitable for all libraries have been widely adopted in medical libraries because they often form part of a bigger library and because they must provide for books on non-medical subjects Mr Barnard has adopted the method which starts with the books themselves and builds up a classification to fit them

First published in 1936, the Barnard classification was originally devised for the London School of Hygiene and Tropical Medicine No less than 8 of the 26 main divisions were allotted to bacteriology, parasitology, and medical zoology, classes which constitute less than a tenth of the stock of most medical libraries The specialties of medicine, which may comprise nearly half of the stock of a medical library, were all compressed into one main class Mr Barnard has now removed this bias by providing an alternative notation The new arrangement is very ingenious and should enable the scheme to be applied in libraries of almost any type

The main schedules of the classification have been thoroughly revised and brought up to date In common with all the major schemes, the Barnard classification provides for further expansion and definition by means of auxiliary schedules and tables

No classification has been (or is ever likely to be) devised which will meet the needs of both general and specialised medical libraries, large and small, but the Barnard classification is an heroic attempt to provide one It has already been adopted by more than thirty medical libraries, including those of the Royal College of Surgeons of England and the World Health Organisation

Maternal Emotions

NILES NEWTON, PH D, research associate in obstetrics, school of medicine, University of Pennsylvania New York Paul B Hoeber 1955 Pp 140 $3

THE researches described in this monograph were concerned with women's feelings toward menstruation, pregnancy, childbirth, breast-feeding, infant care, and other aspects of their femininity Dr Newton has had much experience as a psychologist, working in close association with her husband in the department of obstetrics and gynæcology of Jefferson Medical College, and she records work done over nine years Her own investigations have covered many of the subjects studied, but the references to other work are copious, though limited mainly to American sources

There is no doubt that Dr Newton is anxious to show how important maternal emotion is for both mothers and children She deplores the present progression of American women towards artificiality, and points to the evidence for the satisfaction to be gained from following Nature's methods She gives many useful facts on matters about which there has hitherto been endless argument based on untested assumptions One instance is her tested finding that if a breast fed baby takes his complementary feed (in American, "supplemental feed") from a spoon rather than a bottle, the length of the breast feeding period will be doubled

There are plenty of stimulating ideas for students of obstetrics, natural childbirth, or breast-feeding, and many challenges to pursue or review their work more closely For psychologists, there is a great deal of material in the various appendices setting out methods of approach to the patient

Radiographic Atlas of Skeletal Development of the Knee

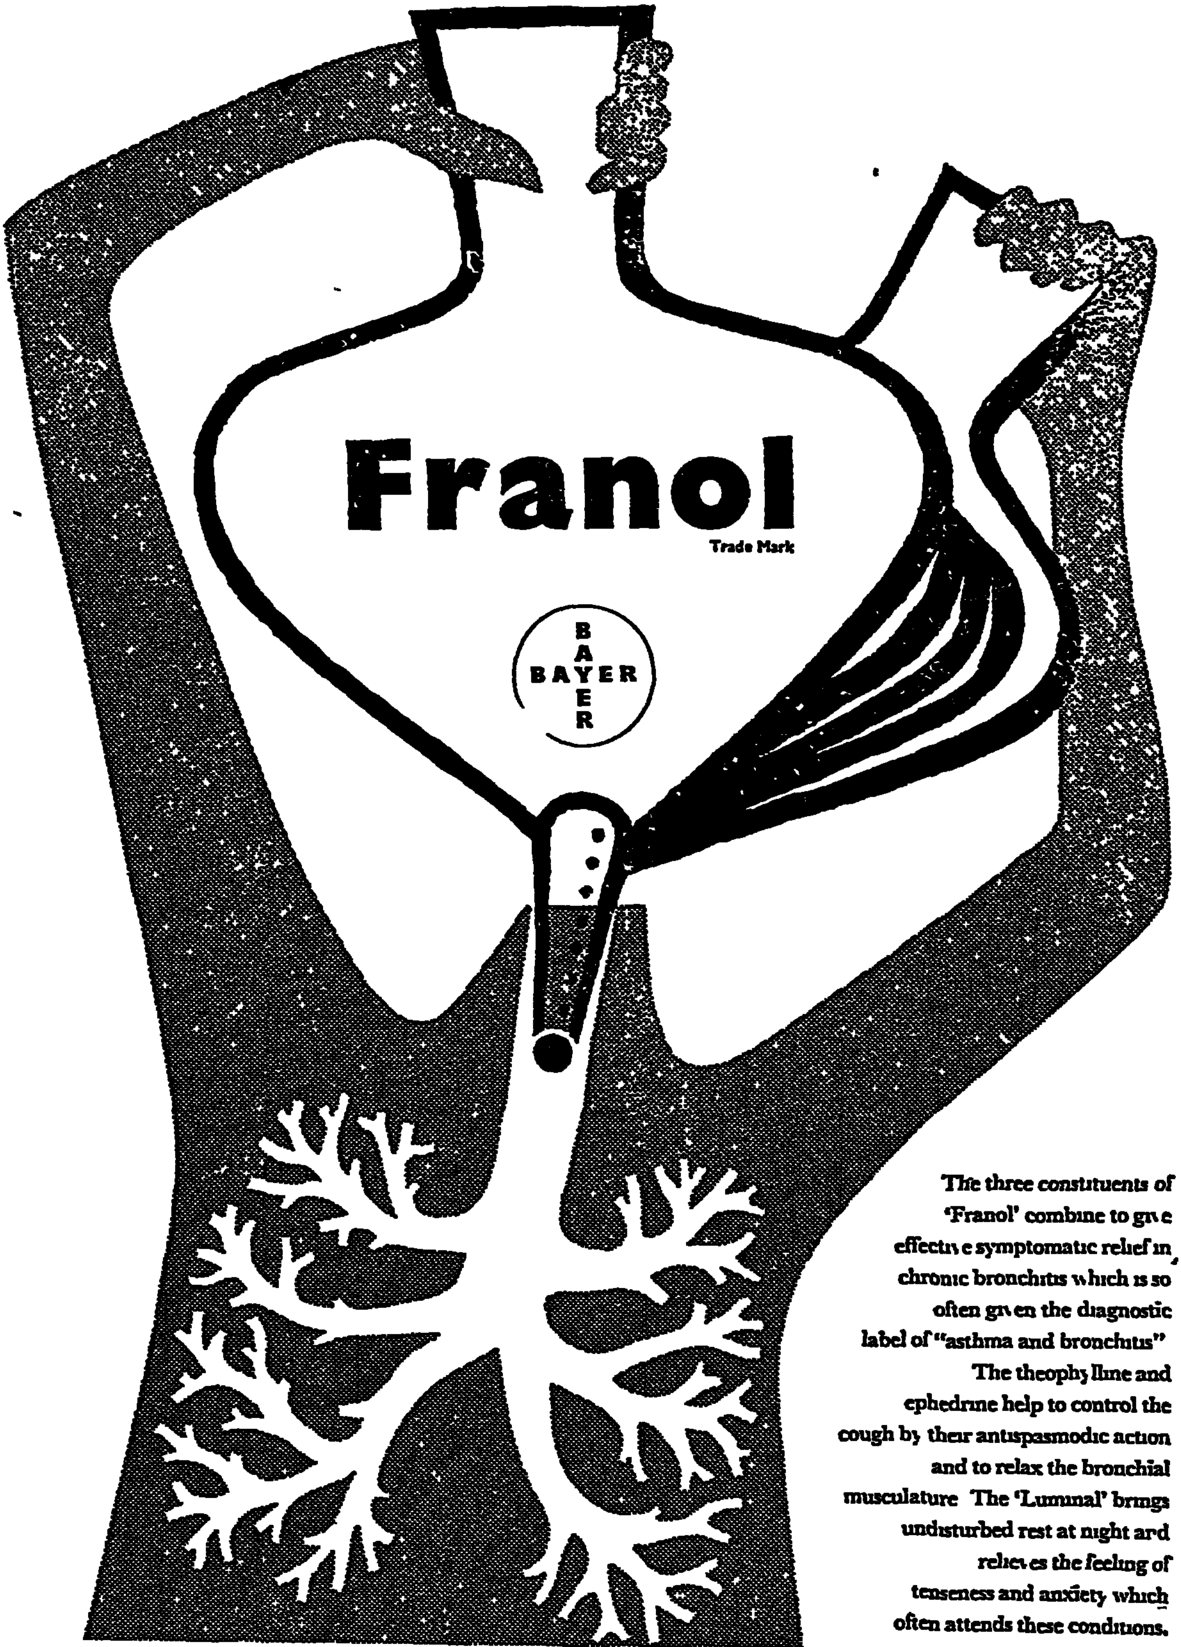
S IDELL PYLE, PH D, NORMAND L HOERR, PH D, M D, department of anatomy, Western Reserve University School of Medicine, Cleveland, Ohio Springfield, Ill Charles C Thomas 1955 Pp 82 31s

THE work recorded in this book was undertaken to produce a standard of reference for the maturation of the knee-joint "for clinical use by a tested inspectional method"

The authors have analysed the various changes in the radiographs of knees during growth, and they reproduce 29 plates which they consider illustrate the normal development of the joint The general production of the book is excellent and the reproduction of the films adequate, but it is difficult to see where its practical value lies or who would find it useful apart from those interested in the minutiæ of skeletal development The changes from year to year in the growing knee seem too slight for confident differentiation, and they depend for their identification very much on the exact positioning of the joint, which may be surprisingly difficult There are easier ways of estimating skeletal age than this

---

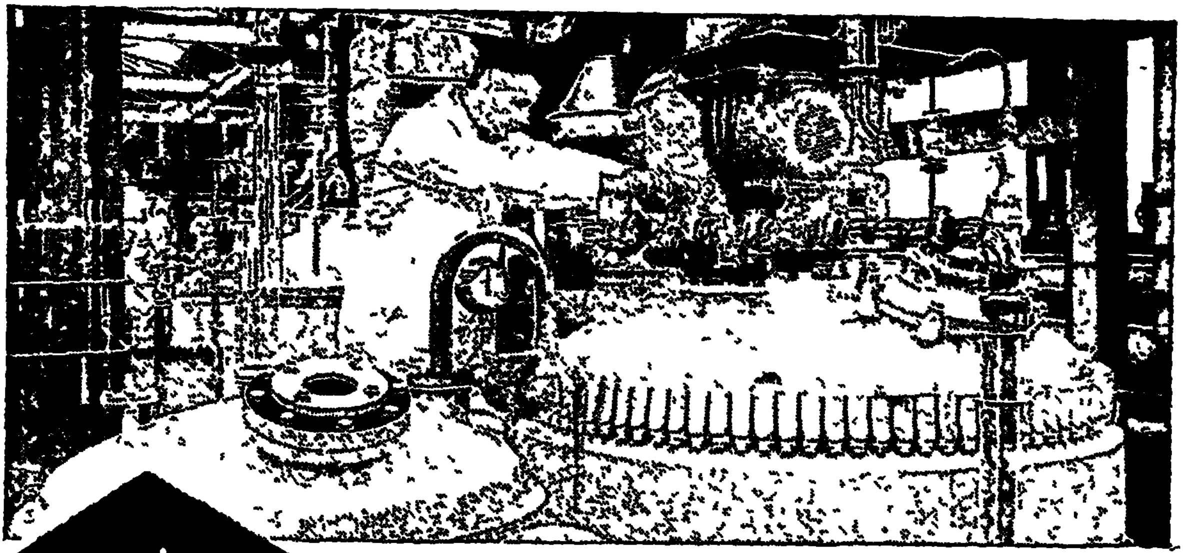
Textbook of Pharmacognosy (3rd ed London J & A Churchill 1955 Pp 578 42s)—Most drugs introduced in the past ten years have been synthetic, but among the new material now included in Professor Wallis's well known text book are sections on *Rauwolfia serpentina* and *Rauwolfia canescens*, the sources of reserpine, on *Ammi visnaga* from which khellin is obtained, and on bentonite which is used in ointment and cream bases For the rest, the third edition retains the lucid text and clear line drawings which have made the earlier editions deservedly popular with students and teachers alike



The three constituents of 'Franol' combine to give effective symptomatic relief in chronic bronchitis which is so often given the diagnostic label of "asthma and bronchitis" The theophylline and ephedrine help to control the cough by their antispasmodic action and to relax the bronchial musculature The 'Luminal' brings undisturbed rest at night and relieves the feeling of tenseness and anxiety which often attends these conditions.

BAYER PRODUCTS LTD NEVILLE HOUSE KINGSTON-ON-THAMES · SURREY

Associated export company WINTHROP PRODUCTS LIMITED

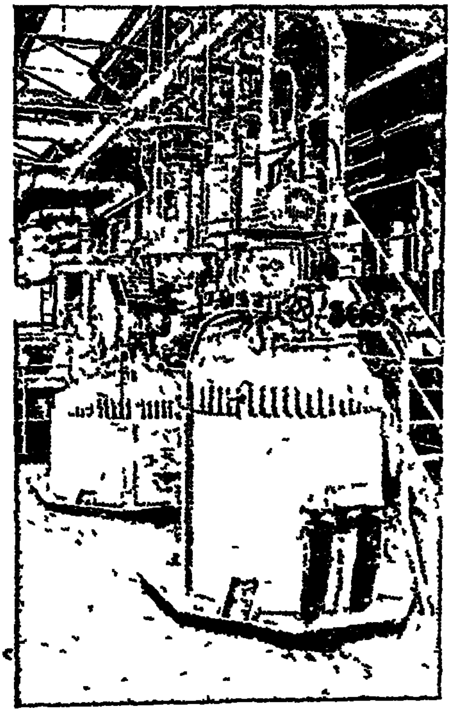


Boots

CORTISTAB and HYDROCORTISTAB preparations

now freely available on prescription

These products are manufactured in Great Britain at our extensive plant, designed for the large scale production of corticosteroids.



CORTISTAB (CORTISONE ACETATE)

TABLETS 25 mg Bottles of 40, 100 and 500
INJECTION 25 mg per ml Vials of 10 ml
EYE DROPS 1% Bottles of 3 ml
EYE OINTMENT 1% Tubes of 3 G

HYDROCORTISTAB (HYDROCORTISONE)

TABLETS 20 mg Bottles of 100
INJECTION (Intravenous) 5 mg per ml for intravenous injection after dilution Ampoules of 20 ml

INJECTION (local) 25 mg per ml Hydrocortisone acetate suspension Vials of 5 ml

Further details will be gladly sent on request to

The Strategy of Medical Research

MEDICAL research in the United States—its achievements and prospects—is reviewed in two fascinating volumes from the American Foundation[1] The second, in discussing the investigation of some of the major problems of the coming half-century, such as virus diseases, atheroma, hypertension, rheumatic disorders, and cancer, is lucid and readable, but the first volume may ultimately be more important, with its account of the activities of research institutes and the organisation of work within them Almost every facet of the complex that makes for medical advance is examined in a study which has been in process for fifteen years and may have as much influence on American medical research as FLEXNER's reports of forty years ago had on American medical education

In organising research the first need is to recognise the born investigator We have only to think of CHARLES SHERRINGTON, J S HALDANE, and their peers, to appreciate that sustained continuity of effort towards a single major objective characterises the work of really outstanding men They usually bring to this work a wide knowledge based on their academic quality, and some early diversity of research interest supplies a breadth of biological and technical experience before they settle down to the task which they make their own The great discoveries often come from observing the significance of some unexpected finding, which turns up in the pursuit of some apparently commonplace inquiry The chance observation of glycosuria in depancreatised dogs led to insulin, the accidental fogging of a photographic plate gave us X rays, and the initial discovery of penicillin was the result of chance acting on "the prepared mind" Hence the danger, to which WIGGERS[2] calls attention, of research "by proxy" in which technicians and junior assistants do the laboratory work In his own circle of acquaintance, WIGGERS says, at least three Nobel laureates did their own technical work with their own hands It is only the inspired investigator, with a feeling for finer detail, who is likely to perceive the potential interest of the unexpected laboratory finding GAUSS, when he was once asked how he had become the greatest contributor to mathematical thought, answered simply "By thinking about *it all the time*"

The growth of team-work, so necessary in the use of our increasingly complex technologies, brings its additional problems There are the difficulties of integrating into a medical team scientists who may not have had even a biological training and are apt to be baffled by the vagaries of living patients and their diseases Again, such may be the difficulties of resolving jealousies between members of the team, and of making use of the total brain-power of the group, that successful leadership is often as much an exercise in social and personal relationships as it is in science

The American writers make a strong plea for the promotion of fundamental as opposed to applied research—a plea the more necessary because problems of immediate importance are more likely to appeal to the laity, who in one way or another must foot the bill It is curious that in the United States, the wealthiest country in the world, medical schools seem to have financial troubles as great as or greater than our own At least half of them are said to have budget deficiencies, or to need large sums to keep up their standards, and yet there are immensely wealthy foundations in a position to spend money on a lavish scale (Perhaps it is not entirely fortuitous that, since these volumes were written, the Ford Foundation has announced its intention to make a grant of 500 million dollars to the American medical schools and associated institutions[3]) Sometimes, of course, the money given by the public can be used only in some specific direction, such as cancer, psychiatry and poliomyelitis, and the public does not necessarily give most generously to the most necessary purposes (A child with a crutch elicits more financial sympathy than a man with a hearing-aid, though deafness may be a much greater total national physical handicap) During years of intimate contact with investigators, research foundations become more sensitive to actual scientific possibilities, but unfortunately they do not pool their experience, and one after another they spend eight, ten, or more years in finding out the disparity between paper planning and actual needs Some of the bodies financing research are apt to think in terms of immediate practical return for money spent, but others, of which the Markle Foundation[3] gets special commendation, concentrate on helping promising men to enter the academic field

The pattern of research is influenced also through direction of government funds, State and Federal The richer States can afford to give their State universities greater freedom, but others insist to a greater or less extent on using the university as a "local service station" Thus in the dairy State of Wisconsin about two-thirds of the problems under study are connected in some way with the economic needs of the State an example is the *study of* enzymes concerned with the ripening of cheese To suggest that such applied research is not fruitful would be wrong it has led, for instance, to the understanding of sweet-clover disease of cattle which had caused bleeding and death of whole herds, and from this to the trial of dicoumarol as an anticoagulant in medicine Indeed, direct governmental interference in research has led to many excellent advances On the other hand, control by politicians has obvious dangers The recent outbreak of political nervousness in the U S A has apparently caused on occasion the abrupt withdrawal of research grants because of unspecified political suspicions, and the authors of this survey recognise that research and the freedom of speculation which go with it cannot flourish in such an atmosphere

America has immense resources, technical and intellectual as well as financial Research is done in university medical schools and allied institutes like the Massachusetts Institute of Technology, under various Foundations (some with their own independent institutes, like the Rockefeller), in self-supporting clinics like the Mayo, in the pharmaceutical and chemical industries, and under the ægis of scientific societies and voluntary health organisations In spite of unevenness and difficulties of integration, medical research proceeds in an immense productive flood In this country our resources are meagre in comparison Nevertheless perusal of this work should make us appreciate the value of our system by which grants to the universities and Medical Research Council are made through the Privy Council and are thus beyond any ill-informed or undesirable political pressures Also, while we should all welcome more money through private benefactors and research foundations, we may recognise that from such sources it may come with too many strings attached Money, as JOHN M RUSSELL[3] says, can sometimes do harm

Hypertrophic Pulmonary Emphysema

THE essential features of hypertrophic pulmonary emphysema are loss of pulmonary elasticity and the disappearance of alveolar septa, but despite intensive investigation in recent years no decisive information about the precise causes has so far emerged Some hypotheses, such as deficient blood-supply to the elastic tissue of the lung and over-stretching of the lungs because of a barrel-shaped thorax, do not now seem worthy of consideration, and the long-cherished view that emphysema was especially common in glass-blowers and players of wind instruments was given its quietus by CHRISTIE[4] in 1939 The suggestion that an inherent defect of elastic tissue is responsible for emphysema[5] is hard to disprove, but any hypothesis should take into account the almost invariable association of hypertrophic emphysema with bronchial diseases such as chronic bronchitis or asthma Coughing and obstruction to air-flow have been put forward as relevant factors Coughing does not seem likely to produce loss of elasticity from overdistension of lung tissue, certainly in the expiratory phase, when the glottis is closed, the intrathoracic pressure rises abruptly as the lungs are squeezed by the thoracic and abdominal musculature, but the pressure on either side of the alveolar septa must be equal, except in the less supported apices, which may bulge outwards Again, during the deep inspiration which follows the expiratory phase, the lungs are no more distended than they are in the course of physical exercise regarded as beneficial Nevertheless, as CHRISTIE[6] has pointed out, it may be that the violent pressure changes to which the delicate alveoli are subjected during persistent coughing may lead eventually to loss of pulmonary elasticity, and in that event the lungs would increase in volume and the thoracic cavity would undergo the familiar enlargement to accommodate their increased bulk But it is difficult to produce satisfactory evidence in proof or disproof of this contention, because patients with persistent cough almost invariably have some bronchial affection producing increased resistance to air-flow, and many believe this is the important factor in the genesis of emphysema, as well as a consequence of it This resistance to air-flow is greater in expiration, and, as an attack of bronchial asthma clearly shows, air may be trapped in the lungs Even so, provided that air is distributed equally to the alveoli, the lung tissue will not be unduly stretched It is certain, however, that in conditions like chronic bronchitis and asthma the obstruction is greater in some bronchioles than others, and GORDON[7] suggested that during inspiration alveoli supplied by normal or less obstructed bronchioles would have to accommodate not only their normal quota of air but also an extra amount to compensate for that which had failed to pass through the more obstructed bronchioles Under these circumstances, although the total volume of air in the lungs would not be excessive, some of the alveoli would be grossly overdistended, and repetition of this process might lead to rupture and loss of elasticity This theory of compensatory overdistension is supported by the pathological finding that in emphysematous areas of lung the associated bronchioles as well as the alveoli are dilated,[6 8] and by the persuasive, if indirect, experimental evidence reported by MEAD et al,[9] to which we recently drew attention[10]

It is possible, however, that further work on the ætiology of hypertrophic emphysema may illustrate the complexity of the subject rather than indicate any simple solution this has certainly been the case in the matter of diagnosis FLETCHER[11] showed that physical examination is an unreliable guide, and KNOTT and CHRISTIE[12] demonstrated that radiological prediction may also be fallacious It is necessary, therefore, to have recourse to the techniques of applied respiratory physiology, but it is uncertain at present which are the best and most practical ones The test which has generally been regarded as most informative is the determination of the proportion of residual volume to total lung capacity, and a ratio of more than 35% is usually taken to indicate emphysema But it is known that higher figures may be reached in older people without emphysema, and the test is too laborious for routine clinical use A reduced vital capacity is generally recognised as of little value in the diagnosis of emphysema, yet, as DONALD[13] has pointed out, the ratio of residual volume to total lung capacity may not be much better, since the total lung capacity in many cases of emphysema is not appreciably increased, and is made up of vital capacity plus residual volume DONALD said that if he were forced to diagnose the presence or absence of emphysema on the results of a single test he would choose the maximum breathing capacity (M B C)—the amount of air the patient can move in and out of the chest in one minute—despite the difficulty of excluding false positives due to reversible bronchospasm It is interesting, therefore, that the M B C and the ratio of residual volume to total lung capacity are among the tests lately assessed by CURTIS et al[14] in the diagnosis of early emphysema They estimated the MBC in 328 patients with pulmonary disease (tuberculosis in most cases) for which pulmonary resection was later carried out Suitable specimens for study were obtained at operation in all but 3 of these cases, and emphysema was demonstrated in 150 The MBC was considered abnormal when the volume was 95% or less of the predicted value and when, in addition, elevation of the spirogram indicated trapping of air On these criteria, the MBC was abnormal in 92 (61%) of the 150 cases of proved emphysema, but it was also abnormal in 22 (12%) of the cases in which emphysema was not demonstrated In some patients with emphysema, the spirogram was raised, although there was no apparent reduction in the volume of the MBC, and this evidence of air trapping came to be considered the more significant factor The ratio of residual volume to total lung capacity was determined in 48 patients with proved emphysema, but in only 17 severely affected patients did it amount to more than 35% of the total lung capacity, and this test therefore failed as a useful indication of early emphysema The timed vital capacity (TVC), a test in which prolongation of expiration is indicated by measuring the proportion of the vital capacity which can be expired in a given time, was performed in 113 patients, 79 of whom had proved emphysema A two-second TVC of 90% or less was considered abnormal, and this was found in 71 (90%) of the 79 patients with emphysema and in 18 (53%) of the others A test devised by Comroe and Fowler[15] to detect uneven alveolar ventilation during a single breath of oxygen was used in 114 patients, of whom 70 had proved emphysema A rise of nitrogen in the expired breath to more than 2% was regarded as abnormal This test was abnormal in 59 (84%) of the patients with proved emphysema and in 20 (46%) of the others The most sensitive indication of emphysema was a combination of prolonged TVC, elevation of the spirogram to hyperinflation level during the MBC test (whether or not the MBC was apparently reduced), and a rising curve of alveolar nitrogen after a single breath of oxygen

These tests are, of course, by no means specific and their practical value will have to be further assessed, but they are all easy to perform, and the first two do not require expensive apparatus Any work which may help the clinician to gather some fruit from the physiologist's tree of knowledge is certainly welcome

Soil, Water, and Cancer

In 1947, Stocks[16] noticed a peculiar distribution of deaths from cancer in Greater London which he could not explain by differences in age groups, social conditions, or number of hours of sunshine This led him to observe that the four London boroughs supplied largely by well water had lower cancer mortalities than most of the boroughs supplied by river water Stocks and his colleagues are continuing their inquiry, into the possible relation between what might be called the geological conditions of habitation and cancer mortality, in the North Wales area They have demonstrated an association between an increased mortality from cancer of the stomach in Anglesey and residence on a particular soil group,[17 18] though this association was less definite for agricultural workers The soil in question, because of the equable distribution of moisture at all levels and at all seasons, has a continuous period of plant growth and biological activity, whereas soils not associated with an excessive cancer mortality are subject to late spring or summer drought due to shallowness or rapid drainage, or they have a long wet season because of poor drainage Earlier work[19] in North Wales and elsewhere suggested that the high organic content of cultivated soils was associated with increased cancer mortality

To overcome the great shortage of drinking-water in the Netherlands, schemes have been suggested for the introduction of river water as the main source of supply Tromp,[20] aware of Stocks's ideas, took note of these plans and decided to study the relation between the physicochemical properties of drinking-water and cancer mortality In Holland, the highest total cancer death-rate for all sites had been found amongst municipalities supplied by river water,[21] and where the water had a high SiO_2 and low manganese and natron content Further studies suggested that a high manganese content of the drinking-water is associated with lower cancer frequencies Recently, Tromp and Diehl[22] have extended their work to a more detailed study of the relation between soil and cancer mortality and especially cancer of the stomach The period studied was 1900–40 The average cancer mortality (all sites together) per decade for persons over 50 years of age was ascertained for the seven principal soil types in the Netherlands These soils range from the acid reclaimed and poorly drained peat soils, through sandy soils, to the more alkaline river-clay type The highest cancer death-rate was found in municipalities situated on peat and reclaimed peat soils and the lowest on river-clay soils Thereafter, for the period 1946–52, they studied the total numbers of deaths from cancer of the stomach in men over the age of 50 living in municipalities on the various soil types As in the case of cancer in all sites, it was found that there was a lower mortality from cancer of the stomach, at all ages, among people living on river-clay soils and a higher mortality among those on peat soils Moreover, the order of frequency in relation to soil was, with one exception, similar to that of cancers of all types

Tromp and Diehl conclude that the association between soil type and cancer mortality is a real one They feel that they have eliminated differences in sex and age grouping which might influence such a relationship They also considered the question of differences in type and character of the municipalities (for instance, rural, semi-rural, and urban) which might have affected the figures Regarding genetic and racial factors, they say that no obvious correlations have been found in the department of anthropogenetics of the Netherlands Institute of Preventive Medicine between soil units and racial groups Nevertheless, in view of the work[23][24] which has shown that cancer of the stomach is commoner among people of blood-group A and is particularly rare in those of group O, they suggest that a study of the blood-groups in the Netherlands municipalities would be relevant to this question They are not prepared to speculate about the causes of the observed correlation between soil and cancer, except to point out that traces of metals in soil, drinking-water, and food (which in the smaller municipalities is mostly locally grown) would be sufficient to disturb enzyme balance, and they seem to have made a start in searching for such trace elements The labour involved in the search will be prodigious

All these considerations bring us back to the old question of how firm can be the conclusions drawn from death-certificates The Dutch workers believe that registration of deaths in Holland is accurate, partly because the secrecy of death-certificates is assured and partly because the mortality data are collected by a very competent organisation, the Netherlands Central Bureau of Statistics They assert that, except in the largest cities the population does not migrate much and that doctors and hospitals do not vary in competence or facilities in different parts of the country We can agree with all these arguments, but there still must be many inaccuracies in death certification without post-mortem examination (and even with it) Despite the evidence of a fairly stable population, changes in habitation must be considerable during a long life and with easy means of transport Perhaps the strongest argument in favour of a soil cancer relationship is its demonstration in two communities as widely separated as Anglesey and Holland

Annotations

MYXOMATOSIS

SINCE October, 1953, man and the rabbit flea (*Spilopsyllus cuniculi*) have contrived to spread myxomatosis through the length and breadth of the land Pockets of countryside have escaped entirely, in other areas the pestilence has passed and the few survivors are beginning to re stock the warrens, but in most farming counties foxes make do with rats, field voles, and even vegetable matter, while buzzards lack the rabbit meat they need to produce the normal 2–3 eggs Some of these changes were discussed not long ago at a meeting of the Mammal Society of the British Isles[1], but we must recognise that the entry of myxoma virus has redrafted the ecological play, and we are watching only the opening scene

Fleas feed on the head and ears of rabbits, and in this country the rabbit flea is the most important vector of the virus Its range is short and it probably cannot spread the disease more than a few miles each month in Kincardineshire, for example, there were many infected rabbits only a few hundred yards—but on the far side of a stream—from a single focus deliberately introduced some months earlier In Australia myxomatosis takes wing on mosquitoes, but here only *Anopheles maculipennis atroparvus*, which may carry virus for six months, is a possible vector Nor can infection be readily induced by mechanical contact, or by contaminated grass or vegetables, and this, no doubt, largely accounts for the absence of the disease in backyard and animal-house The virus still maintains its extraordinary host specificity, and, apart from a few brown hares, rabbits are the only mammals known to have been naturally infected

Our wild rabbit has qualities that will almost certainly ensure its survival, but a virus resistant strain has not yet emerged, and, though immune rabbits have been bred, their progeny are normally susceptible On the other hand, attenuated field strains of virus are well known, particularly in Australia but also in France, and recently recovered immune rabbits have been picked up over an area of 50,000 acres in the Dukeries in Nottinghamshire This attenuated strain is said to kill only about half its victims, compared with the 99% mortality by the strain prevalent elsewhere So far this seems to be an isolated instance, but, should the attenuated strain spread or appear in other areas, both myxomatosis and hordes of rabbits may be permanently with us To avoid this and to increase food supplies, the Minister of Agriculture is pressing on with the designation of rabbit clearance areas in which occupiers of the land must destroy the rabbits or, if this is impossible, prevent them causing damage There is strong financial inducement to farmers to carry out the provisions of the 1954 Pests Act, for conservative estimates for England and Wales show that last year the grain yield in rabbit-free areas was raised by about two hundredweight an acre—equivalent to something over £10 million sterling These are immediate returns, but the eventual gains could be much more striking For those with only an eye for the countryside, ash and oak saplings are beginning to appear where they were scarcely seen before, gorse is shooting prodigiously, grasses are higher, and wild flowers such as cowslip and rock-rose, and even the rarer orchids, have bloomed unexpectedly

CHEMISTRY AND ACTION OF ANTIBIOTICS

THE structure of antibiotics and the way in which they work have lately been reviewed by Regna[1] and Umbreit[2] The term "antibiotic" has come to refer to any chemical substance produced by a micro organism which can inhibit the growth of, or otherwise destroy, other bacteria or micro-organisms By this definition, the first antibiotic was penicillin In the molecule of penicillin the side chain R can have various configurations such as benzyl, pentenyl, amyl, and so on The elucidation of the chemical structure of this molecule was finally achieved by a brilliant and painstaking crystallographic analysis of the molecule,[3] after organic chemists, both in Great Britain and in the United States, had been unable to decide between two possibilities Biosynthetic pathways[4] have been used to vary the group R, and other clinically useful preparations have been devised by salt formation with the free acid group of penicillin (the procaine, chloroprocaine, and ephenamine salts, for example) Penicillin seems to be adsorbed to and thereby deactivates a specific component of the cell wall of the bacterium[5] This inactivation appears to lead to a disturbance in the synthesis and metabolism of the nucleic acids,[6] and this causes, in turn, disturbances in

Penicillin

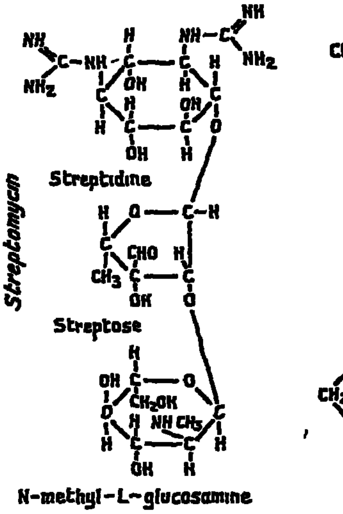
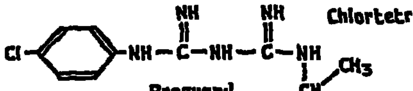
[6] Gale, E F Symposium on Mode of Action of Antibiotics, 2nd Int Cong Biochem Paris 1952

amino acid incorporation and protein synthesis[7,8] But a more detailed understanding of the action of penicillin is still lacking

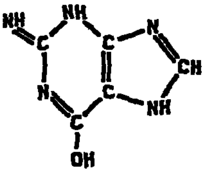
The combination of the unusual 4-membered lactam ring and a hitherto unknown α amino-acid in the penicillin molecule suggested that other antibiotics, as they were discovered, were likely to have structures differing unexpectedly from any of the known groups of natural products This feeling has been amply justified Streptomycin was shown[9] to contain 3 separate moieties (streptidine, streptose, and N methyl-L glucosamine) joined by glycoside linkages The guanidine residues in streptidine recall the active antimalarial drug proguanil ('Paludrine') and the biologically important guanine, which is contained in nucleic acids, streptose and the L glucosamine fragments had not previously been encountered from natural sources The cultures of *Streptomyces griseus* which produce streptomycin produce some closely related antibiotics (mannosido *streptomycin*,[10] *hydroxystreptomycin*[11]) and also actidione[12] which, although inactive against bacteria, is useful for its action against fungi



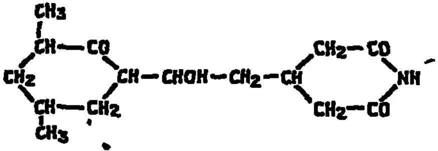
Streptomycin



Proguanil

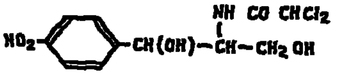


Guanine



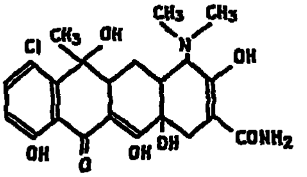
Actidione

In contrast to penicillin, *streptomycin* can be shown to react with a variety of cellular constituents It forms a complex with proteins and nucleic acids, with subsequent alteration in the surface charge on the *bacterium, and* it inhibits several enzyme systems[13] Of these, the oxalacetate pyruvate system appeared to be an important seat of action, and it was found that the formation of a hitherto unknown metabolite, 2 phospho 4 hydroxy-4 carboxyadipic acid,[14] from a dicarboxylic acid and pyruvate was inhibited by streptomycin at dilutions comparable to those required to inhibit growth

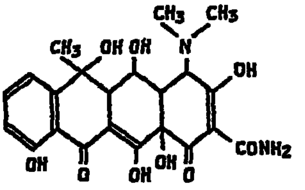


Chloramphenicol

Chloramphenicol has unusual chemical features[15] The molecule contains a nitrobenzene fragment and an amide derived from dichloroacetic acid Although both of these compounds had been known to generations of organic chemists, the isolation of chloramphenicol was the *first* indication that they could be natural products The stereochemical configuration of the side chain is related to D threose and is an absolute requirement for antibacterial activity Chloramphenicol is also unique among antibiotics used clinically in that it can be synthesised on a commercial scale[16] A clinically useful chemical derivative is obtained by esterification of the primary alcoholic group with palmitic acid[17] This ester is slowly hydrolysed in the duodenum, releasing the active principle and thereby providing long sustained therapeutic blood-levels Practically nothing is known about the mode of action of chloramphenicol, but interference with amino acid formation and metabolism is probably not the initial reaction



Chlortetracycline (aureomycin)

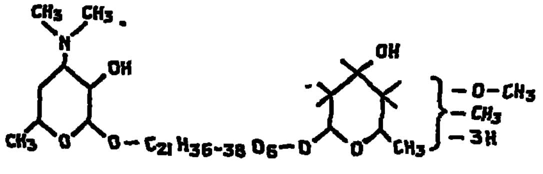


Oxytetracycline (terramycin)

The tetracycline antibiotics, to which chlortetracycline (aureomycin) and oxytetracycline (terramycin) belong,[18] all possess a nucleus of 4 partially hydrogenated 6-membered rings and are produced by species of streptomyces The mode of action of this group is unknown The members of another group, which includes the various tyrothricins gramicidin, and bacitracin, have structures with which the organic chemist is already familiar The family of polypeptide antibiotics which are usually cyclic in structure do, however, contain various amino acids in the D (or "unnatural") configuration For example, tyrocidine A is believed to be composed of the following amino-acids in a cyclic *configuration*[19]

┌—L-ornithine—L-leucine—D phenylalanine—L proline—
│ L phenylalanine—D-phenylalanine—L-tyrosine—L-valine
└————————————————————————————┘

It is interesting that oxytocin, the oxytocic principle of the posterior pituitary, is also a cyclic polypeptide[20] The structures of erythromycin and carbomycin, two of the newer antibiotics, are not known in full, but degradations have been reported,[21] suggesting a partial structure for erythromycin



Erythromycin

The question of how an antibiotic acts and the problems of bacterial resistance[22] are closely related It is probable that bacterial resistance does not necessarily arise as a result of the action of the drug, but that there

are natural mutants which are able to develop and multiply under conditions fatal to the wild type This resistant strain can then be expected to develop mutants which are as well fitted for survival as the original strain

PREVENTION OF JUVENILE DELINQUENCY

So far most attempts to deal with juvenile delinquency have concentrated upon the established condition—correction rather than prevention Yet bad social and economic circumstances need equal attention, and we therefore welcome a report[1] recently published by the City of New York mayoral office which describes a concerted and planned approach, at municipal-authority level, to the prevention of delinquency These measures were based upon sound preliminary research into the backgrounds most likely to promote delinquent trends among young people in New York It was recognised, for example, that there is a need for more guidance and friendly supervision of certain adolescents in their recreational pursuits, and for the education of their parents in handling emotional problems within the family group The report therefore provides for more trained workers in the youth club movement and at community centres on certain housing estates The juvenile liaison department of the City Police Service is also to be augmented to provide more staff for informal contact with the youth in vulnerable districts In education, the report proposes the formation of a pool of senior school teachers, experienced in handling pre delinquent children, and they will circulate among schools in "difficult" localities Certain disabilities, such as backwardness in reading, are associated with delinquency in children of potentially normal intelligence, and the report therefore advocates wide extension of remedial coaching to counteract this tendency Under privileged senior school students, who might otherwise drift into unsavoury associations, are to be encouraged to complete their education, if necessary while working half-time in private industry at prevailing wages The programme for advising and guiding parents, through parent teacher associations, is to be extended by means of informal evening discussion-groups, led by experienced counsellors

These proposals do not depart radically from previously accepted principles No specific proposal is new, and indeed similar provisions, on a more limited scale perhaps, already exist in many places in this country What is noteworthy, however, is the degree of coordination the report advocates the formation of an independent planning committee, which will assess the results of the new drive, so that promising developments can be given further scope, and duplication of effort may be avoided It is in coordination that the report's lesson lies

The New York plan is an expensive one and it would be hard to get approval for spending so lavishly on a comparable scheme for London, for example But it should be possible, without ruinous cost, to do more in support of a vigorous coordinated policy of prevention in this country, and it is good to read in Dr J A Scott's report on the health of London in 1954 that steps are being taken to bring into effect the main recommendations of the L C C study group on preventive mental health in the maternity and child-welfare services[2] What is in fact needed is not so much new services as a re orientation of existing ones and their closer collaboration to avoid overlapping Sir Basil Henriques, in his Peter Le Neve Foster lecture to the Royal Society of Arts last April,[3] made substantially the same point, when he referred to the need for a composite child welfare office in every town and in every district of cities, to contain the headquarters of all statutory and voluntary bodies dealing with the welfare of children Sir Basil's concept of a Ministry of Juvenile Welfare, combining the children's departments of the Home Office, the Ministry of Education, the Ministry of Labour Youth Employment Council, and the Ministry of Health, is not perhaps so fanciful in the light of the New York report it might simply be a national extension of the coordination that New York is seeking on a municipal scale

HYDROCORTISONE FOR URETHRAL STRICTURE

In recent years improved treatment of urethritis has greatly reduced the incidence of inflammatory stricture of the urethra, and, by comparison, traumatic stricture, whether from injudicious instrumentation, long continued catheterisation, or other causes, has become more significant As urethral strictures, whatever their cause, are notoriously hard to treat, there is always a strong incentive to try any novel means of dealing with them In advocating local treatment with hydrocortisone, Bonner and his colleagues[1] in Boston base their method on the ability of hydrocortisone to diminish proliferation of fibroblasts in wounds and on its fibrolytic activity which they observed in established scar tissue They first dilated the stricture as far as possible without danger of rupture, and then an aqueous suspension of hydrocortisone was injected into the stricture at two points on its circumference Meatal strictures were injected directly with a small hypodermic needle, and those more deeply placed were located through an endoscope (under local or general anæsthesia) and injected with a special needle of suitable length The procedure had generally to be repeated once or twice later, according to the response 18 urethral or meatal strictures were dealt with successfully in this way

Compared with existing methods of treatment, the results recorded by Bonner et al are remarkable Much improvement undoubtedly followed the injections in several long standing and resistant strictures, but nearly half the patients in the series had recent meatal lesions which might have done well without hydrocortisone Moreover, cortisone treatment of other lesions of the urinary tract (such as chronic interstitial cystitis, Hunner's ulcer, and Peyronie's disease) has not borne out its early promise, and it would be premature to believe that hydrocortisone is a big advance in the treatment of urethral stricture

RISKS OF BOXING

Speaking to medical officers of the London Amateur Boxing Association on Dec 5, Dr Edwin Clarke said that the 6 deaths of amateur boxers since the war have all been from intracranial hæmorrhage, and the meeting recommended various precautions—that rubber floors should always be used for boxing shows, that a doctor should be allowed to assess the injuries of boys who have been stopped during a bout, that "all cases of prolonged unconsciousness or amnesia after a head injury should be sent immediately to hospital by ambulance", and that the medical officers should be provided with forms on which to notify the boxer's own doctor of any injuries received, so that treatment may be continuous The negative results of electro encephalography in 11 cases were held to show that "the policy of at least four weeks' rest from boxing after a severe head injury is paying dividends"

A few years ago, in reporting rules made by the New York State Athletic Committee,[2] which include the attendance of a doctor at the ringside who can if necessary advise the referee to stop the fight, we took the view

that it is virtually impossible to detect a potential candidate for intracranial hæmorrhage, and we pointed out that though early signs and symptoms of traumatic encephalopathy ("punch drunkenness") may be discovered in veteran professionals, it is rare in amateur boxers Electro encephalography has been used to detect early brain damage,[3] but the results are by no means conclusive and there would be serious difficulties in enforcing this investigation as a routine in amateur boxing

Many people, while agreeing that professional boxers are liable to severe injuries, especially after they reach 30 years of age, maintain that amateur boxing is relatively safe, but Doggart,[4] who describes the eye injuries sustained by boxers, stands four-square against both forms of the sport "Medical supervision" he remarks, "cannot alter the anatomy of the human skull or lessen the delicacy of those organs which subserve our highest faculties," and he quotes the opinion of Carroll[5] that probably no head blow is taken with impunity and each knock out causes definite and irreparable damage He also deplores the effect of boxing on the spectators

HOSPITAL COSTING

As in previous years the Hospital Costing Returns for 1954–55[6] set out the costs for every hospital in the National Health Service in England and Wales under itemised headings The object of these analyses is to enable comparisons to be made between broadly comparable hospitals, in order "to promote economy, increased efficiency and improvements in methods of administration"

The classification of hospitals has been somewhat changed The term "general hospital" has now been replaced by "*acute hospital*", *and consequently a* class by class comparison of costs cannot be made as accurately as in earlier years This, however, is unimportant, for the whole structure of the analysis is riddled with inconsistencies, on account of which comparison between hospitals is virtually impossible—except perhaps in the column "average weekly cost of provisions per person fed," and in the column giving the final over-all figure The greatest source of difficulty is the variation in numbers of outpatients, which are allowed for at an arbitrary cost The ratio of casualty to true outpatient attendances must, however, vary considerably between different districts, and the actual cost per attendance must vary greatly with the type of service given The outpatient cost is allowed for in the final cost column per inpatient bed, but not among the individual items of running costs Until the cost of outpatients and casualties is excluded from the main hospital inpatient analysis these costing tables will remain too full of fallacies for any serious comparisons to be made

In practice, these annual publications are not significantly aiding economy, but they are proving of some indirect value to patients When a difference between two comparable hospitals is studied, there is invariably a good reason for the discrepancy, and usually the difference reveals a need for greater expenditure in the less costly hospital, rather than for reduction in the more *costly one Hospitals* by and large still have a remarkable amount of old-fashioned and extravagant equipment, particularly for heating Again, some hospitals have reduced maintenance to dangerously low levels The general public is perhaps more keenly aware than hospital staff themselves that there is a greater concentration of dangerous organisms in hospitals than anywhere else in the community The low hygienic level still prevalent in some hospitals owing to economy in maintenance constitutes a real danger and is paid for by recurring outbreaks of cross-infection or food-poisoning sometimes with loss of life

It is surprising that indices of comparison, such as "cost per patient treated" and "average length of stay," are omitted, but these figures are available to the regional boards It is very doubtful whether any sufficient purpose is served by publication of these annual tables in their present form They will never bring about true long-term economy What is needed is an over-all figure, together with a few tables free from gross fallacies Each year some aspect of hospital activity could be studied by a true costing system and the lessons published as a guide to policy

LYSINE DEFICIENCY

LYSINE is one of the amino acids essential for man—that is, it cannot be synthesised in the body and if it is not supplied in the diet symptoms of lysine deprivation *occur Osborne and Mendel*[1] *showed* that animals remained alive when gliadin provided all the dietary protein, but they grew only when lysine was added to the diet Deficiency of lysine has also been shown to cause anæmia in animals[2] In humans Albanese and Holt[3] found that experimentally induced lysine deficiency caused negative nitrogen balance, which was reversed as soon as lysine was added to the diet The only woman in their inquiry menstruated during the period of lysine deprivation, and she noted a complete absence of the swelling of the breasts, headaches, and weight-gain which usually preceded her periods This observation is interesting in view of the influence of lysine deficient diets in suppressing the œstrus cycle in animals[4] Albanese et al[5] showed that people on a lysine deficient diet had a greatly increased urinary excretion of non-ketonic organic acids Restoration of lysine to the diet promptly reduced the excretion of these acids to normal During the period of high organic-acid excretion they all complained of nausea, vertigo, and hypersensitivity to metallic sounds

In the body lysine seems to be remarkably inert Thus Schoenheimer and Rittenberg[6] found that lysine was the only amino acid which failed to take up N^{15} when they fed rats with isotope tagged ammonia and various amino acids When *l* lysine tagged with deuterium and N^{15} was given to rats, the lysine of the tissues contained the isotopes in the same proportion as that in which they had been given, although N^{15} from administered lysine was found in other amino-acids But the lysine which was incorporated into the tissue proteins had undergone no chemical change Although lysine can donate amino groups, its main function is in the formation of proteins It is not surprising therefore that Albanese et al[7] have now recorded that lysine added to milk mixtures given to infants had a remarkable effect on weight and nitrogen balance

Currently fashionable fresh or dried milk mixtures were given to 15 children from one to twenty-seven months old After a control balance period, lysine was added to the diet in the form of 100 mg of *l*-lysine HCl per kg body-weight per day *A control series of 9 children* aged two to eighteen months received no lysine supplement During the period of added lysine, 5 of the children on supplemented diets gained in weight and went into positive nitrogen balance, 6 had no spectacular weight gains but went into positive nitrogen balance, and in all these 11 the blood proteins increased The other 4 children in this group, whose growth rate was already above average, showed no response to added lysine Albanese and his colleagues conclude that lysine-fortification will improve the nutritional value of many infant foods, including cow's milk, but that this is only effective with children who are not deriving adequate nourishment from their food They also suggest that whereas the lysine-tryptophane ratio in the diet of young adults necessary for growth is from 2 0 to 3 2,[8 9] the needs of an infant can only be met by a ratio of 6 0 If they are right, it seems that human breast-milk with a lysine-tryptophane ratio of 3 8[10] may be insufficient to meet the growth requirements of infants—and there is no evidence that that is so A more recent report[12] by Albanese et al confirms their earlier findings and suggests a simplified scheme of dosage for feeding lysine to infants

ARTIFICIAL RESPIRATION IN CHILDREN

SOME 120 children under the age of five die in Great Britain each year from drowning, and mechanical suffocation in bed or cradle is given as the cause of death of an even larger number, but this diagnosis is almost certainly wrong in many cases Nevertheless, some of these lives might well be saved if parents were better able to deal with the emergency by applying manual artificial respiration at the earliest possible moment The time spent in summoning help may make the difference between success and failure of artificial respiration Moreover, the aspiration of large amounts of water, especially fresh water, causes profound circulatory changes, hæmodilution, hæmolysis, and ventricular fibrillation[13] These changes develop rapidly and may be the most potent factor in death from drowning, and one of the main reasons why action must be swift

A method of artificial respiration for reviving children must be effective, simple, easy to teach, and not fatiguing to use These requirements have been considered by Rickard,[14] who concludes that there is as yet no satisfactory method for children under two, but for the older ones the now standard Holger Nielsen[15] method is suitable He has therefore proposed a new method for children under two which he has called the "Rickard prone tilting visceral shift method" This is an ingenious use of the rocking principle,[16] which Eve devised when treating a two year old child with diaphragmatic paralysis[16 17] The rocking method is also recommended in children in Garland's excellent handbook[18] In Rickard's method the prone child is laid length-wise along the operator's right forearm with the child's face cupped in the operator's right hand The right middle finger is inserted in the child's mouth, holding the tongue forward, allowing drainage of secretions, and maintaining the airway The patient is steadied by the operator's left hand and is then rocked rhythmically by alternate flexion and extension of the right elbow Rocking begins with a downward tilt of 45°, which produces expiration and expels the aspirate It is continued through an arc of 90° at a rate of eight to twelve times a minute Only experience can show whether this method is effective, but there is no reason to believe otherwise The excellent ventilation achieved with both the Eve and Nielsen methods was demonstrated on curarised anæsthetised adult volunteers,[19] but that experiment should not be performed with the Rickard method If, as seems likely, the method proves to be a valuable one, it should be made widely known

PARALYSIS TREATED BY MUSCLE TRANSFER

THE transfer of a single muscle attachment has been widely used in the treatment of permanently paralysed limbs, but apart from the pectoralis transplant described by Clark,[20] complete muscle transfer has not been recorded Schottstaedt et al[21] may therefore have opened a new field of orthopædic treatment Few muscles, of course, can be completely transposed, and unless the distance to be moved is small, a long and mobile neurovascular pedicle is essential Either the pectoralis major or the latissimus dorsi can be used in this way to provide flexion of the elbow, the insertion of each is transferred to the coracoid process and the origin to the radius The latissimus dorsi can also be used to unite coracoid to olecranon to produce elbow extension The restoration of neck flexion by transposition of the pectoralis major to replace a paralysed sternomastoid, and the use of an intact sternomastoid to replace a paralysed masseter, are each ingenious examples of the art of muscle transposition

Views on the value of tendon transplantation in poliomyelitis are changing, and it is clear that many procedures do little lasting good When complete muscle transposition is performed the strength of contraction may not be great, but further experience of the optimum fibre length for effective action may improve these results Although many patients with severe paralysis may be unable to afford the loss of a large muscle mass, others may find it of great value to have the independence of action which transposition brings

NEW YEAR HONOURS

OF the four new medical knights who work in these islands, Dr Greig Anderson, of Aberdeen, receives his promotion in the Royal Victorian Order by reason of his position as physician to Her Majesty's Household in Scotland, but his knighthood could as fittingly recognise his position among his colleagues and his services to old people Mr Mercer, who in 1948 became the first professor of orthopædic surgery at Edinburgh, was chosen by his fellows in the Royal College of Surgeons of Edinburgh to be their president in this memorable year of the 450th anniversary of its origin Mr Victor Negus, whose name has long been known wherever laryngologists or King's College Hospital men forgather, is a surgeon who has never ceased to be a biologist and has thereby learned much and taught much Professor Zuckerman, of Birmingham, simultaneously anatomist, physiologist, educationist, and much else besides, has combined a fruitful academic career with forms of national service including the study of ballistics in war and the direction of scientific policy in peace Overseas, Sir Arthur de Silva consulting surgeon in Colombo, becomes K C M G, Dr Paul Boffa is knighted for public services in Malta, and Dr S L A Manuwa, descendant of rulers and now chief medical adviser to the federal government of Nigeria, adds the honour of knighthood to the many others he has gained since the day in 1926 when he graduated at Edinburgh In congratulating these and many other doctors whose names appear on p 40 we must also express the pleasure that many will feel at the knighthood conferred on Mr George North, LL D, who as Registrar General has shown himself so helpful a collaborator in the work of our profession

THE EPIDEMIOLOGY OF LUNG CANCER IN NEW ZEALAND

DAVID F. EASTCOTT
M B Lond., D.P.H.
ASSISTANT DIRECTOR, NATIONAL HEALTH INSTITUTE, WELLINGTON, NEW ZEALAND

New Zealand is insular and remote. It was discovered and occupied by Polynesians about a thousand years ago. In the fourteenth century there was a major Maori invasion, and from then until the coming of Captain Cook in the late eighteenth century New Zealand had practically no contact with the rest of the world. This means that Europeans did not settle in the country until the mid-nineteenth century, and that when they did so they came (as they have continued to come) predominantly from Great Britain. Consequently persons, other than those of Maori extraction, born in New Zealand are predominantly of British descent.

Immigration has generally been continuous, and there exists in New Zealand today a numerous group of immigrants from Great Britain who can act as natural controls, being essentially of the same stock and now living under similar conditions and differing only in the fact that they have spent part of their lives in Great Britain before coming to New Zealand. Moreover, it is possible to divide these immigrants into groups according to their age on entry and hence according to the degree of exposure to another environment before coming to New Zealand. If this different environment which they experienced during the earlier years of life had an effect on the risk of contracting cancer it should be reflected in differences in mortality between those born in New Zealand and those born in Great Britain and between those in the immigrant group who came to New Zealand after a substantial period of residence in Great Britain and those who came at an earlier age.

Method

This study was made on deaths from cancer of various sites in immigrants from the United Kingdom and in the New Zealand-born non-Maori population in 1949–53. The population at risk was taken as the Census Population of 1951. It was confined to those aged 35 or more.

Expected deaths were calculated on the basis of these figures and the significance of differences between the expected and observed deaths was assessed in terms of χ^2.

TABLE I—EFFECT OF "URBANISATION" ON DEATH-RATES FOR CANCER OF VARIOUS SITES

Areas arranged according to degree of urbanisation	All sites except lung			Stomach			Large intestine			Rectum		
	No. of deaths observed	No. of deaths expected	Degree diff.	No. of deaths observed	No. of deaths expected	Degree diff.	No. of deaths observed	No. of deaths expected	Degree diff.	No. of deaths observed	No. of deaths expected	Degree diff.
Total	7646			1353			1000			451		
Auckland Urban Area	1413	1363.9		223	238.1		169	180.4		81	80.1

Degree of Difference Column

The percentage difference between the expected and observed numbers of deaths is represented by the following equation

$$\frac{\text{Observed no. of deaths} - \text{Expected no. of deaths}}{\text{Expected no. of deaths}} \times 100$$

Where (a) expected number of deaths is less than 20
or (b) percentage difference is less than (i) 5% for "all sites except lung" } the column is left blank
(ii) 10% for other sites
Where percentage difference is (i) 5% but less than 10% for "all sites except lung"
(ii) 10% but less than 20% for other sites—it is noted by – or +
Where percentage difference is (i) 10% but less than 15% for all sites except lung
(ii) 20% but less than 30% for other sites—it is noted by – – or + +
Where percentage difference is 30% or more it is noted by + + + –

Immigrants tend to settle more often in towns than in the country, in the larger towns than in the smaller, and in the North Island more often than in the South Island. It has been reported from other parts of the world (Stocks 1947, Spiegelman 1952) that the incidence of certain forms of cancer is higher in some regions than others in accordance with the degree of urbanisation. The data were therefore used in the first place to assess whether any similar differences existed in New Zealand. For this purpose the following areas were chosen: the major urban areas of Auckland, Wellington, Christchurch, and Dunedin, with populations near to, or greater than, 100,000; aggregates of other urban areas in the North and in the South Islands with populations of 20,000 or more; and the remaining areas in each of the two principal islands. Comparisons between towns and localities were based solely on deaths in those of New Zealand birth, and were, of course, allocated to the usual place of residence of the deceased.

The following sites were considered at first, as well as deaths from cancer of all sites: stomach, large intestine, rectum, lung and bronchus, breast, cervix uteri, prostate, and skin (other than malignant melanoma). Important unequivocal differences were found, however, in lung and bronchus only. It was therefore decided to take out figures for other parts of the respiratory tract. Accordingly larynx was added; and tongue, mouth, and pharynx were taken together.

Comparison was based on the actual and expected deaths for each of the sites chosen in the age-groups 35–, 45–, 55–, 65–, and 75+, the expected deaths being calculated in each locality on the basis of the rates for the New Zealand-born population as a whole; the figures for the separate age groups were then added together.

The only site that showed consistent differences in mortality in the areas considered was lung and bronchus, where a significant increase with urbanisation was shown in both males and females (table I).

Though a consistent or significant urban bias is not seen in the separate sites other than lung, there is such a bias for all other sites taken together. It is smaller than in the case of lung but, in view of the numbers involved, may be considered significant.

Accordingly, in assessing differences between those who were born in New Zealand and those who were born in the United Kingdom, the expected deaths were calculated for each area and then added together to allow for differences in the geographical distribution of the immigrant population compared with the indigenous population, though such differences in practice were found to have a negligible effect on mortality for any site other than bronchiogenic cancer.

TABLE II—OBSERVED AND EXPECTED MORTALITY FOR CANCER OF CERTAIN SITES ACCORDING TO WHETHER BORN IN NEW ZEALAND OR BORN IN THE UNITED KINGDOM

Site of cancer	Where born	Observed no of deaths	Expected no of deaths	Significance of difference between observed and expected*
All (less lung)	N Z	7646	7628.4

Findings

The numbers of deaths of New Zealand born persons and of immigrants from the United Kingdom, and the expected deaths of the two groups on the assumption that there is no difference in the incidence between them, are given in table II.

The assumption holds good for all forms of cancer except that of lung and bronchus. In the latter site the immigrant group has a much higher incidence of bronchiogenic cancer than would be expected on the basis of equity, suggesting that for this site, and this site alone, the immigrant has an increased susceptibility.

The United Kingdom-born were next divided into two groups according to the age at entry into New Zealand, those under 30 at the time of entry being placed in one group and those aged 30 or more being placed in the other group. There was a small residue of persons whose age on immigration had not been stated.

The observed deaths and the deaths expected on the hypothesis that age at time of entry to New Zealand has no effect on the risk of dying are shown in table III.

There is nothing to conflict with this hypothesis in any site except again lung. For all cancer, other than of lung and bronchus, taken together there is a suggestion that the incidence is higher in those who were over 30 on immigration; the difference, about 5% above the expected value, is of doubtful significance. It is not of the same order as the 46% seen in the case of the lung. Possibly the difference is partly due to exclusion of a few persons whose age at entry was not stated. Such persons numbered 14 in the case of lung and bronchus, and 76 for all other cancer; the number of immigrants from the United Kingdom whose age at entry was not stated at the time of the census in 1951 was 1723.

Lest it might be thought that a similar consideration can explain the difference in the case of cancer of the lung, all 14 persons whose age on entry was unstated were allocated to those who were under 30 at the time of immigration, and the 1723 of the population whose age at entry was likewise unknown were allocated to those who were 30 or over when they came into the country. This minimises the difference between the two groups, but it is unlikely that the persons concerned would be distributed in this extreme manner. Nevertheless the difference is still found to be significant, the observed and expected values now become as follows

Age at entry	*Actual deaths*	*Expected deaths*	*Significance of difference*
Under 30	201	229 2	0 01 > p > 0 001
30 or more	168	139 8	

Discussion

Immigrants to New Zealand from the United Kingdom have a higher incidence of lung cancer than New Zealand-born persons of the same stock The difference is greater in those who were aged 30 or more when they came to New Zealand This increased incidence is unlikely to be an artefact, for it is not seen in any other of the principal sites for cancer Moreover, it is the same for women as for men and is consistent at all ages over 35 and for all the principal parts of the country

The chances of dying of cancer of the lung are 30% higher for all United Kingdom immigrants, but for those who were 30 years of age or more on entering New Zealand the risk is 75% higher This is in agreement with the differences in the death-rates from cancer of the lung in the two countries (see table IV)

There has been a continued increase in New Zealand in the numbers of male deaths at all ages certified as due to lung cancer, but the incidence has always been substantially below that in England and Wales The peak of incidence in England and Wales is in the age group 55–64 during the two earlier periods, whereas in New Zealand it has always been in the group a decade older

Owing, at least so far as New Zealand is concerned, to the small numbers involved at the extremes of the age-distribution shown, deaths from lung cancer in females are subject to much random fluctuation There appears, however, to be little if any increase in those below the age of 45, but there is a steady increase thereafter The New Zealand figures roughly parallel the English figures, but, as in the male, the death-rates are well below those in England and Wales

The conclusion follows that immigrants from Great Britain to New Zealand are affected by their former environment and that this effect is related to the length of exposure in that environment It shows itself in an increase in lung cancer but not in cancer of any other site

Differences in habits of tobacco smoking are unlikely to contribute to this picture Consumption of tobacco in the two countries for the first half of this century is shown in table V

The environmental factors concerned are unlikely too to be of a personal kind related to the way of life of the immigrant, for this would make it difficult to explain the differences between the younger and the older immigrants

The evidence points to the factors being associated with urbanisation, as has been suggested in other studies (Kennaway and Kennaway 1951, Stocks 1952) It shows too that they may exert their carcinogenic effect a long time after the person has been removed from them, and this is in keeping with what is known of the mode of action of the carcinogens isolated from the atmosphere of industrial cities (Leiter et al 1942, Waller 1952)

TABLE IV—AVERAGE YEARLY DEATH RATE PER MILLION PERSONS FROM CANCER OF THE LUNG 1932–53 IN NEW ZEALAND COMPARED WITH ENGLAND AND WALES

VITAMINS OF THE B COMPLEX

THE nutrition panel of the food group of the Society of Chemical Industry held on Dec 14 the second meeting of a series concerned with Nutritional Requirements and Food Fortification[1] Vitamins of the B Group were dealt with under nutritional requirements, dietary supplies, and food fortification

Dr H M SINCLAIR discussed nutritional requirements He said that the B M A figures covered requirements for the average person but individual requirements were affected by race, age, sex, and the other components of the diet The type of carbohydrate affected the requirements of thiamine by influencing the intestinal flora In addition the state of health might affect the absorption (for example, in pernicious anæmia, or by losses through vomiting and diarrhœa) and the use (for example, in fever and hyperthyroidism)

Thiamine was required for the oxidation of carbohydrate at the level of 0 4 mg per 1000 calories The requirements were increased considerably in old age, the reason for this was unknown The requirements of *riboflavine* were affected by alterations in the amount of fat and protein in the diet, probably because of change in the intestinal flora Although there was no evidence that the requirements were linked to calorie expenditure the B M A 's recommendations suggested 0 6 mg per 1000 calories On the other hand the U S National Research Council linked the riboflavine requirements with the protein intake, but Dr Sinclair pointed out that there was no clear reason for doing so Nicotinic acid was required for the oxidation of fat and carbohydrate, and the recommended intake was 4 mg per 1000 calories The requirements were influenced by the level and type of protein in the diet since tryptophan could be converted into nicotinic acid Carcinoid tumours produced large amounts of serotonin from tryptophan, and pellagra developed in some patients because of this loss of tryptophan Nothing was known of the requirements of vitamin B_6, but deficiencies did occur and diets were probably marginal Peripheral neuritis had been observed in tuberculous patients treated with isoniazid, due to combination of this drug with pyridoxine, and possibly many other drugs could behave similarly

---

Miss A M COPPING dealt with dietary supplies The average intakes of thiamine, riboflavine, and nicotinic acid were a little above the recommended average intakes About a third of the thiamine and nicotinic acid were provided by bread and cereals, and 40% of the riboflavine by milk and cheese Since much of the B vitamins in wheat was contained in the outer endosperm and germ, the B vitamin content of flour increased with the extraction rate Other members of the vitamin-B complex, including B_6, B_{12}, biotin, and folic acid, were fairly widely distributed in foodstuffs and were likely to be in reasonable supply, although nothing precise was known as to the requirements

Thiamine was partly destroyed by heat, especially in alkaline solution, and the Ministry of Food tables allowed 15% for the loss of this vitamin Riboflavine was relatively stable to cooking, but was destroyed by light, and milk exposed to light lost a considerable amount

Mr J B M COPPOCK, PH D, discussed food fortification The present white loaf, which appeared to be preferred by the public, was fortified with thiamine and nicotinic acid to the level of these vitamins found in flour of 80% extraction In the United States levels of enrichment were about three times those enforced in this country, and included the addition of riboflavine, Dr Coppock suggested that British practice was restoration rather than enrichment

The enrichment of rice with thiamine was carried out by soaking rice grains in a solution of the vitamin and adding 1% of this master mix to the main bulk of the rice The alternative was to spray the rice with a solution of the vitamin protected by a film coating which resisted washing

Dr Coppock pointed out that serious losses of vitamin B_1 occurred during the washing and cooking of rice, amounting to 20–90%, and there was, on the average, a 20% loss on baking bread Recent work had shown that this loss occurred with patent and whole-meal flour and was independent of prior treatment with bromate or chlorine dioxide The losses seemed to depend solely on the temperature reached, thus, in the case of toast, losses were greater with thinner slices The loss of thiamine in bread, cake, and biscuits was related to the internal temperature reached during baking Dr Coppock pointed out that the thiamine content of bread, after allowing for baking losses, was little more than adequate for the calories contained in that bread and did not provide any excess for the rest of the diet The fall in bread consumption suggested the need for an upward trend in fortification

In the discussion Dr SINCLAIR pointed out that the removal of nutrients and the restoration of only some of these nutrients was unsatisfactory For example, deficiencies of pyridoxine might arise, and pantothenic acid was essential to man, and the National loaf contained seventy times as much manganese as the 70% extraction loaf In reply to a question whether riboflavine should be added to the white loaf, Dr Sinclair said that the conference on the post war loaf had agreed not to add this since bread was not an important source of riboflavine, contributing only 12% of our intake He pointed out that in poor families with many children bread would be a more important source of riboflavine, and when asked his opinion he agreed that this vitamin should also be added to white bread

Mr A E BENDER, PH D, asked what levels of intake of vitamins were desirable to ensure not only that the average intake was above the required level but that the greater part of the population received more than this level Miss D F HOLLINGSWORTH replied that this question could not be answered since so little was known of the individual variation both of requirements and of intake She added that the intake of riboflavine did not include the losses in milk exposed to light

In reply to a question on the influence of different carbohydrates on the intestinal flora, Dr SINCLAIR said that there was experimental evidence that thiamine deficiency developed more readily with sucrose in the diet than with starch or glucose Volunteers on a diet deficient in vitamin B_1 had shown signs of deficiency when the carbohydrate was sucrose but not when it was dextro maltose This was apparently due to synthesis of the vitamin in the gut

NEW YEAR HONOURS

THE list of honours published on Jan 2 contains the names of the following members of the medical profession

K C M G

SIR ARTHUR MARCELLUS DE SILVA, O B E, F R C S
Member, Public Service Commission, Ceylon, consulting surgeon, General Hospital, Colombo

K C V O

ALEXANDER GREIG ANDERSON, C V O, M D, LL D Aberd F R C P

Knights Bachelor

PAUL BOFFA, O B E, M D
For public services in Malta

SAMUEL LAYINKA AYODEJI MANUWA, C M G, O B E, M D, LL D Edin, F R C S E
Chief medical adviser, federal government, Nigeria

WALTER MERCER, M B Edin, hon F A C S
Professor of orthopædic surgery, University of Edinburgh, president of the Royal College of Surgeons of Edinburgh

VICTOR EWINGS NEGUS, M S Lond, hon D SC Manc, F R C S, hon F R C S E
Consulting surgeon, ear, nose, and throat department, King's College Hospital, London

SOLLY ZUCKERMAN, C B, B A Cape Town, M D Birm, D SC Lond, F R S
Deputy chairman, Advisory Council on Scientific Policy, Sands Cox professor of anatomy, University of Birmingham

C B (Military)

Major General FREDERICK CAVENDISH HILTON SERGEANT O B E, M B Lpool, Q H P

Surgeon Rear Admiral ROBERT CYRIL MAY, O B E, M C M R C S

Major General FRANCIS JOSEPH O'MEARA, M D Dubl, F R C P I, Q H P

C B (Civil)

EDWARD ROLAND ALWORTH MEREWETHER, C B E, M D Durh F R C P
Senior medical inspector of factories, Ministry of Labour and National Service

C M G

JAMES LESLIE MCLETCHIE, O B E, M B Glasg
Director of medical services, Eastern region, Nigeria

GEORGE DOUGLAS ROBB, M D, CH M N Z, F R C S, F R A C S
Consulting surgeon, Auckland, New Zealand

KOK CHEANG YEO, M D Hong Kong
Director of medical and health services, Hong Kong

C V O

STAFFORD ERIC SAINT, M R C S

C B E (Military)

Air Commodore GLEN ALBYN MARTIN KNIGHT, M B Melb, R A F

C B E (Civil)

JOSEPH EDWARD DEBONO, M D Malta, F R C P
Professor of medicine, University of Malta, for medical services in Malta

HUGH MONTAGU CAMERON MACAULAY, M D Lond
Senior administrative medical officer, North West Metropolitan Regional Hospital Board

CHARLES GEORGE MCDONALD, CH M Sydney, F R A C P
Consulting physician, Royal Prince Alfred Hospital, Sydney, New South Wales

CHARLES TITTERTON MAITLAND, M D Lond, F R C P
Principal medical officer, Ministry of Health
ROLAND NIGHTINGALE, M B Manc
President of the Association of Certifying Factory Surgeons factory doctor for Stockport district
LAWRENCE WILLIAM PLEWES, M D Toronto F R C S E
Consulting orthopædic surgeon, Luton and Dunstable Hospital
HENRY CAMPBELL WILKINSON M D
Lately director of health services, Bermuda
KATHARINE GEORGINA LLOYD WILLIAMS, M B Lond F F A R C S
Dean, Royal Free Hospital School of Medicine, London

O B E (Military)

Surgeon Commander HERBERT LEWIS BELCHER, M R C S, R N
Lieut -Colonel AUSTIN BERNARD DEMPSEY, F R C S, R A M C
Lieut Colonel TERENCE RICHARD JANSEN, M B E, E D, Ceylon Army Medical Corps
Lieut Colonel DOUGLAS DUNDAS MAITLAND, L R C P E, R A M C

O B E (Civil)

GERALD HENRY COORAY, M B E, M D Lond
Professor of pathology, University of Ceylon.
THOMAS DAVIES, B SC Lond and Wales, M R C S
Chairman, medical recruiting board Cardiff Ministry of Labour and National Service
KENNETH FRASER, M D Edin
County medical officer, Cumberland
RICHARD JOHN BURNSIDE HALL, M B N Z, F R C S E, F R A C S
Medical superintendent, Cook Hospital, Gisborne
WILLIAM CHARLES BURKE HARRISON, L R C P I
Director of medical services for Northern Rhodesia, Federation of Rhodesia and Nyasaland
JOHN SWINTON MEREDITH, M B Glasg
Medical specialist, Tanganyika
WILLIAM LEATHLEY NICHOLSON, M B Manc
Senior medical officer, Ministry of Pensions and National Insurance
WILLIAM MATHIAS QUIN, M B Edin, F R C S E
Lately senior surgical specialist, Sierra Leone
CHARLES MCCONAGHY ROSS, M B
Senior leprosy officer, Northern region, Nigeria
IAN NORMAN SAMUEL, M R C S
For political and public services in Battersea
HAROLD GRIFFIN VASE, M R C S
Chairman, Royal Air Force Benevolent Fund Committee in Jamaica

M B E (Military)

Captain HAMISH COATES NEALE, R N Z A M C

M B E (Civil)

ROBERT ASHLEIGH GLEGG, M D Edin
Hon secretary, East Sussex County Housing Association for the Aged
HARRY HAIGH, M B Camb
For medical services, Eastern region Nigeria
GLADYS CHEE ING HU
For medical services in Singapore
CENYDD RICHARDS JONES, M B Wales
Amerindian medical officer, British Guiana
EMERIC LOSONCZI, M D Naples
Medical officer of health, British Honduras
ALEXANDER GOW MEARNS, M D Glasg
Senior lecturer, department of public health and social medicine, University of Glasgow
DOREEN ANNE MURRAY, L R C P E
Resident medical officer, Colony Hospital, Granada, Windward Islands
OWOLABI ANIFOSHE OMOLOLU, M B Edin
School medical officer, Lagos Federation of Nigeria
GEORGE EDWARD RANAWAKE, M R C S
Secretary, Hospital Lotteries Board, Ceylon
JAN ZYGMUNT SLOMINSKI, M B Polish Sch Med, Edin
District medical officer, Carriacou, Windward Islands
EDMUND NATHANIEL OYEKANMI SODEINDE, M D
Senior medical officer (clinical), Federation of Nigeria
CONRAD EVAN ELWIN STEVENS, M B Belf, F R C S E
Medical superintendent, Cunningham Hospital, St Kitts, Leeward Islands
WILLIAM ERNEST STORK WINN, L R C P E
For public services in Kandy, Ceylon

The Widdicombe File

XXX THE MEDICAL CURRICULUM

DEAR WILL,

You ask me to write to your young nephew and to give him some idea of what he will have to expect during his studies if he should take up medicine Nothing would give me greater pleasure—but only if I had as interesting an account to give him as you generously but quite wrongly assume that I must have For the truth is that his curriculum will be surprisingly similar to that from which you yourself emerged with distinction 25 years ago Because the curriculum is still very much what it was there's only one thing that I'd like to tell him, and it's this work well enough to pass but do not overwork to gain distinction

Defenders of the curriculum sometimes argue that those who criticise it are merely saying that there are many disappointing students—many who are lazy or too poor in intelligence or general education to get much good from any course of study But I refute that with three pieces of personal evidence

First, our students' medical society—bless it—has been sending its members to departments, for elementary demonstrations and discussions, as much as one and two years before they reach the subject in question in the normal course of their studies Over and over again I have heard my colleagues say what I have myself observed—namely, that the students show far more keenness and are far more observant and able to discuss things well at these early informal demonstrations than when, one or two years later, they come to the subject as a class They are steadily losing interest

My second bit of evidence is that I have taken on as assistants a number of men whose undergraduate records were far from good, although none of them was rank bad Some have remained only moderate performers, but more of them have suddenly come to life, confessed to a first awakening of interest in their books, and shown that—freed from our teaching and *examination* programme—they had it in them all the time to be really keen students of medicine

Thirdly, what effect has the curriculum on those who bend themselves the most willingly to its demands and manage to stay the course to the end? Three of our year, you will remember with modest pride, attained the eminence of graduating with distinction

Pringle, the first of us in the order of the prize-lists, went straight off to be house surgeon to the professor —Honest John—and was so disillusioned by that good man's ignorance that he pledged himself to the physiology department as soon as his year in hospital was up Unfortunately he had worked so hard and so *consistently* as a student that he was, unknown to himself, dangerously sensitised to professors and textbooks—with the result that he left physiology in 3 months to take a job in an obscure provincial hospital, from which he has not moved to this day He is now a *full time* consultant physician and is known locally as a sound chap with a surprising range of knowledge But he never publishes anything, he does no research, and he makes too little use of his brilliant gifts for analysis of really hard problems and for logical exposition His *undergraduate* devotion to the curriculum killed his fire and arrested his intellect You may say that making himself a distinguished student cost him his academic soul

I need not dwell on my own story, for you know it in full But I should remind you that for 8 years after graduation I went from one thing to another, mighty uncertain what I wanted to do and finding nothing that I was keen to work at with real devotion At that stage my experimental probing took me back to a post in our old school, but I should pretty certainly have left that also if I hadn't been given leave of absence to join the Army at the outbreak of war Six years in different parts of the world and in an extraordinary variety of situations seemed to neutralise most of the harm which I suffered from being a *diligent student* *After the war I returned* to my hospital and academic duties with real zest for the work, and my life would now be a thing of unclouded happiness if only I could adjust my expenditure to the hard fact that my net income is less than half of my gross earnings *But seriously I should estimate that it* required 8 years of restless seeking and a war to rescue me from the harm that was done to me from taking the curriculum seriously

You yourself, to all appearances, suffered least of the *three of us from your medical studies* For you laughed off your academic distinctions as an outrageous fluke and went straight into general practice in your own village I think that you came off best because in fact as a student you followed your own curriculum and indeed learned your *medicine in your long vacations* You dodged all the poor lecturers, although you went to practical classes and clinics , but I never saw you around the hospital in the holidays When I stayed with you in the summer of 1928 I remember that you then had two chief activities *outside your duties as a fast bowler for the village eleven* all unqualified, you took Dr Battersby's surgeries and made a great many of his visits on any day when he and his friend the village stationmaster concluded that the water and the wind were right for trout-fishing , and sitting in the study of the Rev William Smart, you composed thrilling sermons which that wise old gentleman was glad to deliver after he had purged them of their worst heresies By these vacation activities you gained for yourself two things that the curriculum could never have given you first, a real acquaintance with the whole problem with which the illness of one of its members confronts a family , and second, a taste for, and training in, the use of books and periodicals and the orderly expression of your thoughts

Modern developments, of course, have *probably* made it dangerous for you to let your nephew attend your patients until he is qualified and has joined a medical defence society They have probably also deprived you of a railway station and thus of a companion with enough control of his summer days to go fishing with the doctor And I should not be surprised if most parsons think it better to write their own sermons, because of the news value that now attaches to their pulpit indiscretions —as well as to their others, which have always been good for *two half columns and a photograph*

So your nephew may necessarily be thrown back on the curriculum, and it's just what it was before except that it now demands one year extra before graduation and two before *registration* *It allows less free time for personal* study, and has led to examinations that more searchingly probe a student's store of facts but less certainly ascertain whether he can safely be trusted with a patient's life

For years now the Faculty has been listening to pleas *for a few more hours for this, and for many more hours for* that Each teacher applying for more time has a good case who can deny a *plea based on the evident truth* that a great deal more is now known about nucleic acids, steroid hormones, chemotherapeutic agents, viruses, psychiatric disorders, anæsthetics, neurosurgery, isotopes, radiology, neoplasms, and all the rest ? If the teacher is a good fellow who seems likely to make a lively impact on the student, the Faculty gives him most of what he asks for , if he's a *fairly ordinary pedagogue* he is given a half or less , and if he seems a dull stick he's turned down flat or kicked around the subcommittees until his *plea is lost* So there is a certain rough justice and often approximate wisdom in what the Faculty does

But there's never *real wisdom* *For we never—or very* seldom—cut anything out Worst of all, we never ask ourselves what we think we are doing Last week I went to the Faculty with a plea for a little more time to let me deal half decently *with the fundamentals of* antibiotics and viruses Conscious of, and feeling rather guilty about, what I was doing, I coupled my plea with the proposal that the Faculty members should meet informally—without anybody's requests specifically before them—so that *we could tell each other*, in five minutes each, what we were aiming at in our teaching and roughly what ground we each covered I thought that we might then be able to see my plea, and those of others, in perspective I hoped we might face it that we are now asking 7 years *of a boy's life after he leaves school* before we turn him into his 2 years as a National Service medical officer I hoped that we might recall that we once made quite good doctors in 5 years and even in 4 years Every one agreed in principle There was even a witty suggestion that we could *probably* devise a 3-year curriculum if we sent each professor out of the room in turn and left the others to decide how much time his subject required I said that I was seriously worried about merely adding to the students' burden by asking for extra teaching time even *for new topics of obvious importance*—but they gave it to me out of the " free time " My proposal for an informal meeting was turned down because, as the anatomist truly said, so radical an examination of the curriculum would certainly need more than one *meeting*

But surely we shall have to face it Much as I personally shrink from change, I believe that we must turn things upside down because I think that our curriculum is now a bad one I believe that students should be seeing at least a few *patients in their first year of study*, and hearing something about nucleic acids in their last , *I think that lecturers capable only of dictating notes* must be proscribed , *and I think that we should need* at the most 5 years of undergraduate study (including that *for the first* M B) and 1 postgraduate year as a resident in hospital before registration I believe that we must examine the case *for a basic minimum* of study *for all, with the rest of the curriculum set out as* elective courses with the subjects in sensible groupings *I think* that we must give the student greater incentives to study on his own and more chances to take fully responsible care of patients I'd like to see the General Medical Council decree a 20 year period of experiment on these lines, leaving schools *to work out their own solutions* Details of these experiments would, of course, be made known to the G M C , and the results could be assessed by visitors and perhaps by some form of national examination conducted anonymously and based upon methods of testing *separately knowledge of facts, capacity* for self expression, and ability to deal with clinical problems as presented by the cases of actual patients

We have had enough deliberation about better medical education Our discussions have led us from fairly unsatisfactory to bad Are we to leave it to our American colleagues to make the only modern experiments in medical education ? *Let us agree the objects of our* own experiment and for goodness sake let us get on with them, each school making in all probability some *horrid* mistakes and some real discoveries

If we enter such a phase of experiment I'll write an enthusiastic letter to your nephew But if we rumble on as at present I'll only caution him *that he must* weigh the examinations carefully to ensure that he does not suffer from exposing himself innocently to our gross over instruction which certainly leads to progressive and visible dis education Unless we are ordered to mend our ways—for we seem *incapable of doing it* ourselves—he must do all that he can to side step the results of our excessive earnestness and *defective imagination*

Yours,
James Davey

Public Health

REPORT ON ATMOSPHERIC POLLUTION

THERE is no doubt that this country's air has been increasingly polluted during the past fifteen years by grit and dust there is less certainty about the increase in pollution by smoke and oxides of sulphur and the recent report[1] of the Department of Scientific and Industrial Research contains some contrary evidence in that it records a small decrease in pollution by smoke and sulphur oxides The report summarises the results of over a million measurements made during the past ten years—measurements made by local authorities and other organisations cooperating with the department's fuel research station The number of these "measuring" authorities has lately shown a welcome increase from 80 to 220, and the number of measuring instruments in regular use has risen from about 200 to nearly 2000 The department deserves much praise for accomplishing the heavy task of analysing and collating this mass of measurements

The amount of pollution of town air may be as much as forty times that in rural areas, and at times of smog the average level of pollution by smoke and sulphur may reach ten times the normal for the time of the year There may be some increase in air pollution in country districts which goes undetected, for the huge power-stations which now consume much of the nation's coal throw out by forced draught through their high chimneys oxides of sulphur and not a little dust, to be windblown perhaps for many miles The majority of measuring instruments are at present in congested towns, and there is a need for more measurements in rural areas In addition more daily-recording instruments are required so that important basic knowledge may be gained and serious smogs studied in detail

Many of the instruments already in use are designed to investigate particular local sources of pollution such as steel, chemical, and cement works, electricity-generating stations gas and coke works, various industrial boiler installations, railway-engine sheds, and colliery spoilbanks It is good to read in the report of greater coöperation from industrial undertakings responsible for the emission of pollutants an increasing number of industries are recognising their contribution to air pollution and some are taking the public more and more into their confidence

Measurements of air pollution are also of value to central and local authorities in their various building and development schemes Knowledge of the present levels of pollution is a help in planning for smoke abatement, and it will be of interest, when the "smoke control areas" envisaged in the Clean Air Bill come into operation to assess the progress made towards safer air It would be particularly useful to select one or more towns and make them entirely smokeless, thus providing a valuable means of studying the effects on health of a decisive reduction of air pollution

An important result of the London smog of 1952 was the establishment of the committee on air pollution under the chairmanship of Sir Hugh Beaver and the Department of Scientific and Industrial Research gave the committee valuable help Among the important recommendations of the Beaver Committee was the extension of research into the many problems of air pollution and health This would mean a considerable expansion of the research staff engaged in studying the relationships between various pollutants and the incidence of disease Already some special surveys on the influence of air pollution on bronchitis, lung cancer, and other respiratory diseases are being assisted by the department

Over five million tons of sulphur dioxide are discharged into the air of Great Britain each year, and this subject will need intensive examination. By each of our large electricity-generating stations as much as a million tons of coal may be burned each year Another problem in which the department has helped and can help further is that of the tens of thousands of hand-fired boilers still used in industry—boilers which are not equipped to burn raw coal efficiently without producing excessive smoke The special smoke-eliminator door developed by the fuel research station is inexpensive and simple to operate, it makes coal "work harder" by using it more efficiently, and it greatly reduces smoke

Among other work described in this important report, there is that relating to the removal of oxides of sulphur from flue gas, the production of coke that will give a satisfactory fire even on an old-fashioned fire grate, research on domestic heating, and the testing of equipment, one of the objects of which is the more widespread use of stoves and grates that will allow a satisfactory smokeless fire with ordinary coke

London's Health in 1954

In his report[1] for 1954 Dr J A. Scott, county medical officer of health for London, refers to the increase in notifications of dysentery The figure of 4268 notifications in the year was the highest ever recorded The epidemic was already under way when the year began and came to its peak in April The heaviest incidence was among children of preschool age, but there was a slightly increased proportion of cases among school-children compared with the previous year Food-borne outbreaks of dysentery are at present very uncommon, and there is no evidence that the heavy incidence of recent years is due to food infection An investigation of cases in 1952-53 showed that children under 15 were more likely to give rise to secondary spread, and more susceptible to secondary spread than those over 15 Nearly half the cases notified had a clinical illness which was confirmed bacteriologically; less than a tenth were symptomless carriers, and two-thirds were in outbreaks of 2 or more associated cases A clear association was shown between the severity of the primary case and the resulting spread Where the infection was widespread, "sulphonamide appeared to present few advantages"

The *birth rate* was 15 2 per 1000 population compared with 15 3 in 1953 and 1952, 15 6 in 1951, 15 7 in 1950, and 13 4 in 1938 The birth rate, though well in excess of the pre war and early war years, seems to have stabilised at a little below the average of the last 21 years Since 1948 the stillbirth rate has remained relatively stable, and in 1954 there were 19 8 stillbirths per 1000 total births

Since 1951 there has been a steady decline in the *death-rate* to the lowest figure ever recorded in London—10 7 per 1000 population in 1954 Heart-disease accounted for nearly one third of the mortality and although the death-rate from cancer showed a slight decrease from 2 34 per 1000 in 1953 to 2 31 per 1000 in 1954, it remained the second leading cause of death (a detailed examination of the course of lung cancer in London over the last 25 years appears as an appendix to the report)

The *infant-mortality rate* continued to decline and reached the lowest recorded figure of 20 7 per 1000 live births, compared with 23 9 per 1000 live births in 1953 Of these, 15 1 occurred in the first four weeks of life, which was also a record low figure and compared with 17 8 for England and Wales

The total number of women *who died as a result of pregnancy or childbirth* (including post-abortion deaths) was 34, compared with 37 in 1953, 50 in 1952, and 42 in 1951

The number of cases of *diphtheria* continues to decline, and in 1954 there were only 4 confirmed notifications and no deaths There was a smaller incidence of *whooping-cough* than for some years past and there were only 4 deaths from this disease The notifications of *scarlet fever* were the lowest recorded since 1941 and there were no deaths The fatality-rate for *measles* has declined considerably in recent years, and from the 7445 cases notified in London only 2 deaths resulted

---

[1] London County Council Report of the County Medical Officer of Health and Principal School Medical Officer, 1954 Pp 231 2s 6d

The report includes a detailed account and statistical data relating to recent trends in the mortality and morbidity of tuberculosis in London. About a century ago nearly one-fifth of all deaths in Londoners was due to tuberculosis, in 1950 the proportion had fallen to a thirtieth and in 1954 to a fiftieth. 77% of the deaths in 1954 from all forms of tuberculosis occurred among persons aged over 45 years, and the majority (79%) of these deaths were in men.

The routine vaccination by B C G of tuberculin-negative 13-year-old school children was inaugurated during the year. About 25% of parents withheld their consent to vaccination. Of the children whose parents consented to vaccination, only 15% of those not in contact with a known case of tuberculosis were found to be positive reactors.

There was a slight though welcome improvement in the "immunity state" of London children under 5: the number of primary immunisations against diphtheria increased from 36,004 in 1953 to 47,621 in 1954. At the end of 1954 it was estimated that 55% of children under 5 had at some time been immunised against diphtheria. In spite of the fact that no special publicity was given to whooping-cough immunisation, the demand for it continued to grow and during the past four years it had increased fourfold. The number of children vaccinated against smallpox in their first year of life has almost doubled since 1949, and during 1954 about a half of all children under 1 were vaccinated.

Safeguarding Agricultural Workers

Based on some of the recommendations made in 1949 by the Gowers Committee on health, welfare, and safety in non-industrial employment, the Agriculture (Safety, Health and Welfare Provisions) Bill[1] now before Parliament enables the Agricultural Ministers to make protective regulations.

These may deal, among other things, with the safeguarding of workers from dangerous parts of machines, with the training or supervision of young persons when working with prescribed machines, and with the protection of workers from the risk of falls and strains. The maximum loads which workers may lift under different circumstances may be specified. The Bill also provides for notices to be served requiring the provision of sanitary and washing facilities, and the Ministers may make regulations for the provision of movable sanitary facilities where workers are employed by a contractor or other person who is not the occupier of the land. In addition the Bill provides that children under 13 years of age may be prohibited from riding on or driving prescribed vehicles, machinery, or implements used in agriculture. (Local authorities are at present empowered to make by-laws concerning the conditions in which children, after their 13th birthdays and until they leave school, may assist in any trade or occupation.) All agricultural units are to have a first-aid box whose contents will be laid down by regulations. Regulations may require the notification and keeping of records of accidents and certain diseases connected with agricultural work. The Bill also makes certain rules concerning inquests on deaths which may have been caused by agricultural operations.

Colouring in Food

A supplementary report,[2] presented to the Food Standards Committee by their preservatives subcommittee, on the use of colouring matters in foods was published on Dec 21. In an earlier report,[3] published in January, 1955, the main recommendation was that the Public Health (Preservatives, &c, in Food) Regulations, 1925–1953, should be amended so as to permit the use in foods of specified colours only. The present position under these regulations is that, with a few specified exceptions, the addition of colouring matters to articles of food is permitted. The supplementary report reviews the representations which the subcommittee have received from trade and other interests. It sets out in greater detail than in the earlier report the subcommittee's views on the declaration of the presence in foods of added colour, and it recommends a slightly modified list of permitted colours. In other respects it reaffirms the earlier recommendations.

In the list of permitted colours, the report recommends the inclusion of two additional colours of natural origin, titanium dioxide and ultramarine, and there seems, it says, no objection to the continued use in foods of the other organic colours of natural origin customarily used in foods. In view of the need for certain coal-tar colours a revised list of synthetic colours recommended for inclusion in the permitted list is given in an appendix.

The earlier report recommended that in general the presence in foods of added colour should be declared to the purchaser, but it was recognised that exceptions might be necessary. In the supplementary report recommendations are made as to the form the declaration should take, the sales in respect of which declaration should apply, and the foods which need not be required to bear a declaration of added colour.

Before deciding, in consultation with other Ministers concerned, what action should be taken on its recommendations, the Minister of Agriculture, Fisheries and Food will consider any further representations from interested parties.

Representations already made to the subcommittee need not be repeated, but new representations should be sent to the Assistant Secretary, Food Standards and Hygiene Division, Ministry of Agriculture, Fisheries and Food, Great Westminster House, Horseferry Road, London, S W 1, to arrive not later than Jan 31.

Medicine and the Law

Right to Case-records

To whom do case-records belong—to the patient or to the doctor or hospital authority? The point arose recently when a woman was charged before a Metropolitan magistrate with stealing documents, said to be her own case-papers, from St Mary's Hospital, Paddington.[1]

The prosecution solicitor said that the defendant came for treatment at the hospital and took the papers from a table in an office while a doctor was being called. She took them home, and they were found there by the police. The hospital authorities, said the solicitor, were in an embarrassing position because the papers covered a long and difficult case in which civil proceedings had been threatened on several occasions. They wanted to establish that a patient had no right to confidential papers of this character.

For the defence, it was submitted that a hospital patient had the same right to his or her papers as a solicitor's client; the removal of the papers could not be larceny. The defendant had thought that she needed them in order to get treatment and because she wanted the information they contained.

The magistrate said that no one was going to hold in that court that a patient had a right to his or her records. *Prima facie* the documents must be the property of the hospital; until the matter was disposed of they should be handed back to the hospital, leaving the accused to take such action as she would be advised to secure possession of them. The magistrate suggested that the prosecution should withdraw the charge and he would direct that the papers should be returned to the hospital to be kept in safe custody until the ownership was decided by legal proceedings. This course was adopted.

The position as between solicitor and client is stated thus in Halsbury's *Laws of England*:[2] "Documents coming into existence in the course of business transacted under a retainer, and either prepared for the benefit of the client or received by the solicitor as agent for the client, belong to the client; but documents prepared by the solicitor for his own protection or benefit, and letters written by the client to the solicitor, belong to the solicitor."

In England Now

A Running Commentary by Peripatetic Correspondents

Bridge is an Easy Game is the title of the book which Iain Macleod published in 1952 Its theme is the ACOL system, which makes bidding easy for your partner and difficult for your opponent Many doctors are good bridge-players and the best doctors make conditions easy for their partners, give disease, which is the opponent, as difficult a chance as possible, use finesse where necessary, and respect conventions The best bridge-players reach their slams by agreeing on the suit, showing their strength with the minimum of bids, and then using cue-bidding or some convention like the 4–5 no trump or Blackwood convention Having arrived at the right contract bad or indifferent play can undo all the good of the bidding and lead to a post mortem which may be tedious but may help the player not to repeat his error

The best physician suspects a particular organ is at fault, or an infection is at work, investigates it appropriately and not with the full fury of every conceivable test and perhaps calls in his surgical partner for help If, by careful team-work, they decide that a person has an adenoma of the bronchus, or of the islets of Langerhans or a meningioma of the cord, or perhaps, with the help of the bacteriologist, decide that the patient has typhoid or psittacosis, their satisfaction is as great as the slam-bidder's But operation or treatment must be as precise as the play of the cards and the experienced operator or physician has yet to complete his task If operation fails, the post mortem may be revealing If the physician fails in his diagnosis, the patient may seek other advice and the second physician make the right diagnosis His chagrin is like that of the bridge-player who bid five hearts over four spades to save game or rubber and goes three down vulnerable, 800 points, only to find later four spades could easily be defeated Bridge may be an easy game for the real experts and medicine may also be easy at times, but let us never forget that basic principles have an overriding importance over investigations and that administration is an integral part of the profession's work And let us be thankful that for three years at the top of the administration we have had a player bold enough to study new methods, use finesse, and realise that the doctor-patient relation calls for real partnership In his new task his recent experience should help and so let us sincerely wish him the best of luck

* * *

Christmas week has been most confusing Sunday was recognisable—just church followed by over-eating, but then chaos set in Deutero-Sunday coincided with crypto-Monday, and was followed by pseudo-Monday Some found Wednesday normal while others confused it with iso-Monday On retro-Saturday sporadic cases of acute inversion of sleep rhythm heralded an explosive epidemic which raged throughout proto-Sunday and had died out again by midday on Sunday Monday of the New Year saw the normal calendar comfortably restored

* * *

On Christmas Eve there was a knock at the door and I heard a boy's clear voice asking permission to sing a carol I brought him into the lounge and said I would accompany his songs on the piano He was a genuine Christmas-card chorister with a skin of strawberry and milk and an expression of indestructible innocence He started with *Sleep Holy Babe* and sang with a clear reedy voice that would have brought tears to the angels Then he sang *Once in Royal David's City*, and finally the *Coventry Carol* I would have kept him singing all night, but knowing that he had only a little time in which to amass a fortune I asked my wife to bring in the mince-pies I poured him out a sweet sherry and searched in my pocket for half a crown I had to exercise some restraint not to give him five shillings After he had downed the pies and sherry he bent down and patted my golden Labrador on the head

"Hallo Su" he said

"How do you know my dog?"

"I know him quite well He chased me out of your "

"Don't tell me you are the wretched and degenerate youth who stole every apple from my *only* apple tree!"

The truth was too clear I turned helplessly to my wife "I have brought this shining youth into my house out of the cold of the night I have treated him like a princeling I have given him my finest vintage sherry and stuffed his pockets with silver only to learn that he is a monster of iniquity!"

The boy's head sank in an agony of remorse Slowly he opened his hand and offered me the half-crown back "No, my holy innocent—but before you go you will sing every verse of *The Lord at First had Adam made*—unaccompanied"

* * *

This week looks like marking the end of an epoch in our village They are going to fill up the hole in the road It has been there since three years last Christmas, something to do with one of those new-fangled sewage schemes that so disrupt the English way of life The steam-roller came clattering down the hill last Monday and is belching impatiently behind the vicarage Six barrels of tar and a load of granite chippings lie waiting on the village green—the green which has borne three cricket seasons and two and a half football seasons of the contractors' lunch-hour sport We feel just as the Britons did when the legions were packing up for Rome A tampon of tarmacadam will be a miserable placebo for the gap in our hearts

How different it was when the first lorry-load of men came to the village in 1952 and picked a spot outside the *Rose and Crown* It was thirsty work and only the landlord was pleased But Irish tongues and twinkling eyes, and the jingle of half-crowns on pay-night, softened the chill of the tap room The hay season was good the following year, the evenings warm and friendly By autumn time old George's battered taxi was rarely free of white ribbons and confetti Unfamiliar names crept into my midder bookings, Murphy and O'Brien, and even Pinzarelli A fine lot of christening parties we had, with a tot of the real proper peaty stuff for the doctor Too bad that one or two lucky lads got back across the sea, but we are a broad-minded lot in our village, quite used to our own English game of trial and error, so Mildred and Daphne were worked off on someone else, with a flying start for a dowry

We shall miss them all in lots of ways The odd hand scalded while making the nine o'clock tea The sciatica before the local races Mike O'Leary was shaping up nicely as a spin-bowler on Saturday afternoons Pinzarelli clipped the privet hedge around the surgery with the artistry of Michelangelo Poor simple Alf will soon be out of a job He used to twiddle the stop-and-go sign on the corner Nobody took much notice of it, of course, except the day he twiddled it too late and we had to jack the vicar's car out of the hole Mrs Ugglethorpe's paraffin sales will slump when the little red lights are snuffed out for the last time The *Rose and Crown* will seem cheerless

The hole might well have been there for another three years if the boss's son had not come back from his National Service He was a gangling pimply youth when he pegged out the claim, and he never really had a decent chance to get to know us before he was whisked away into uniform Now he has come back, bronzed and broadened, but contact with the wider world seems to have made him strangely intolerant of our hole Can you wonder that we are heavy-hearted?

* * *

I had called for some hair-oil, and found myself standing behind an anxious mother, I distinctly heard her ask for "Delinquent pastilles, please" The chemist looked mystified for a moment and then handed her a packet When she had gone, I could not resist asking him to resolve the mystery To my relief I found that the medicament required was Gee's linctus pastilles

News from the breakfast table

Jane (aged 13) "I am going to paint the dolls' house these holidays and sell it Then with the money I could buy at least two budgies"

Hugh (aged 9) "Do I get a share?"

Jane "No!"

Hugh "I don't think that's fair After all I helped to bring the dolls up"

Letters to the Editor

RECRUITMENT FOR THE OVERSEA MEDICAL SERVICE

SIR,—There is a certain amount of uneasiness about the future of what until recently was called the Colonial Medical Service. May I inflict on your readers some reflections of an amateur that have a bearing on the problem? *

The Present Situation

Although the Oversea Medical Service is still fairly healthy there is a shortage of doctors in certain territories, and in some places, such as Northern Nigeria, it is serious.

Owing to the progress of some dependencies towards home rule, and, ultimately, complete self-government, a career in Colonial medicine (as in other branches of the Colonial Service) is now robbed of some of its former security and of prospects of advancement for the competent man. It is doubtful whether the type of medical officer now being recruited is on the average quite as good as formerly. Not very long ago it was not unusual to find men who, although not perhaps shining lights academically, were energetic, independent, adventurous, and anxious to use their talents in places where they could make their weight felt. These men were the backbone of the service. Some recent recruits are able, but others would have had little chance of success in the United Kingdom in the fiercely competitive conditions that have prevailed since the war and seem likely to continue.

At the same time there is a surplus of good men in the United Kingdom. Some of them, especially those with a little knowledge of the opportunities for work in Colonial territories, would welcome a spell of duty overseas provided—and this is the crucial qualification—that they could be assured of a reasonable prospect of finding suitable employment at home if and when they decided to return.

Indigenous medical services are growing apace, and in a number of territories there are promising medical schools. Thus, so far as the British graduate is concerned, the service is steadily shrinking. It may therefore be asked what need there is to consider a problem that will solve itself within a generation or less. It is, however, clear that for a number of years to come British doctors should continue to help in building up medical services that are still defective and leavening those that have already achieved autonomy or will soon do so. It would be lamentable if the Oversea Medical Service, as we know it, disintegrated in haphazard fashion during the next ten years.

Recent information about resignations in West Africa is disquieting. That the service will contract is certain, but it is possible to make this an orderly involution rather than a rout. The introduction of the Oversea Service last year in place of the Colonial Service was a welcome step, but one cannot help wondering whether the remedy was too little and too late.

The Proposal

The Oversea Medical Service should be abolished. Each territory would continue to have its medical service which would be recruited locally or by secondment from a new Oversea Division of the National Health Service. In some cases the staff would be entirely autochthonous, in others the majority would continue for a time to be supplied by the United Kingdom.

The rates of pay in the Oversea Division of the National Health Service would be the same as in the existing health service plus whatever allowances were appropriate. Salaries would be paid by the National Health Service, the necessary funds being derived from contributions from the various territories supplemented as required by an allocation from the Colonial Development and Welfare Fund. The purpose of this allocation would be to ensure that in poor countries the rates of pay for overseas officers would be as good, or almost as good, as those in wealthier territories. Furthermore, it would be desirable to stabilise establishments so that they would no longer be subject to disconcerting fluctuations dependent on factors such as the prevailing price of coffee or sisal. Each territory would indicate to the Colonial Office, and, through it, to the Oversea Division of the National Health Service, what vacancies it wished to be filled from the United Kingdom. If a man chose to make his career in Colonial medicine he could apply for transfer to a local medical service, if he were prepared to take the risk, or for transfer (see below) to the permanent staff of the Oversea Division of the National Health Service.

The Difficulties

These are formidable and the list that follows is far from exhaustive, but no worth while administrative change can be made without a good deal of pain and suffering.

If one of the cardinal features of this scheme is that men may come and go between the United Kingdom and the oversea territories, then by far the biggest obstacle is the fact that the National Health Service is not unified so far as the appointment of medical officers is concerned. This important function has been wisely delegated to boards of governors of teaching hospitals and to regional hospital boards. The Ministry of Health as such can make no promise of reappointment to a man who is seconded for service overseas. This is the main reason why the regulations made to facilitate secondment proved unfruitful. The power of appointment is in the hands of the boards, many of which know little about the Colonial Service and care less.

An outstanding man whose pioneer work in a remote colony was fittingly recognised by Government returned to the United Kingdom at the conclusion of his three year contract. He was well known to his regional board and held in high esteem by his professional colleagues. All were aware of the duration of his term of service overseas. Yet on his return he was kept waiting for about nine months before he found employment, and it is possible that he might have been even worse off if pressure had not been put on the board from outside. This sort of thing is discouraging.

There are two possible solutions. The ideal but difficult one is that boards should agree to accept responsibility for filling vacancies in particular territories. The Hospital for Sick Children (Great Ormond Street) already undertakes to supply a registrar for the pædiatric service at Kampala, Uganda. However, the chances are that a single teaching hospital or regional board would find it impossible to supply the men with the necessary inclinations and qualifications for particular vacancies as they arose, or, even if the men were found, it might be impossible to guarantee appropriate vacancies for them on their return. Yet this system of adoption, as it might be called, has the merit of evoking personal interest and the pride of relationship. For that reason it may be better than the alternative and ought not, perhaps, to be lightly dismissed.

The alternative is that when the Oversea Division of the National Health Service is asked to supply medical officers for this or that territory it should notify *all* boards of governors and regional boards, these would submit to the Oversea Division the names of men who wished to be considered and for whom places would be available at the end of their term of service overseas An arrangement of this kind would be utterly valueless unless the boards, already overworked and often harassed, entered enthusiastically into this new and onerous responsibility They would need to learn something about the Colonies, but it is possible, and even likely, that if the ground were well prepared the boards would respond favourably And it happens that the Colonial Office can now command the services of a number of medical folk in this country with a good knowledge of Colonial medicine who would be willing to acquaint boards of governors and regional boards with the great significance of the new departure

---

* The policy proposed is in line with that advocated in September, 1953, by a special correspondent to the *Times* and in letters contributed to that newspaper in October, 1955, by Sir Reginald Saloway, Mr Julian Snow, and Mr John Tilney.

Another serious objection to the scheme is that it tends to replace a regular army by one made of men serving on short term commissions Many of the hard-won benefits of unification of the service would be lost Yet it should be possible to maintain a corps d'elite of men who have decided to devote their lives to Colonial medicine and who could be transferred, as at present, to key posts in any territory as the need arose Within the Oversea Division there would be an enclave for such men, still paid by the United Kingdom Government, with regular grades of promotion, but with no guarantee (any more than at present) of their being appointed to posts at home on resignation or retirement

If the course outlined above were limited to medicine —and no more is suggested—it might be objected that the more or less uniform pattern of Colonial administration was being badly shaken The system described could not indeed be easily applied to other professional services because there is nothing in other professions wholly comparable with the National Health Service Here is the test of the value of these proposals If they are worth while, then administrative tidiness should not be taken too seriously And it may be pointed out that however neat the present pattern of central administration that in the territories themselves becomes increasingly kaleidoscopic, with the introduction of officers recruited locally, the direct appointment by Colonial governments of doctors from foreign countries, and the evolution of health departments responsible to elected ministers Even the semblance of uniformity is going, the loss of a little more would of itself do no harm

The Colonial Office would rightly feel reluctant to delegate responsibility for the selection of men for service overseas to another Government department which has little knowledge of Colonial affairs and is, indeed, still busy wrestling with the manifold problems presented by a huge and still young health service It should not be beyond human wit to devise machinery whereby the Secretary of State for the Colonies continued to exercise ultimate authority It would be of benefit to the Civil Servants in his department (as well as to those responsible for the National Health Service) if there were some broadening of selection committees Selection committees set up under the National Health Service, though still not ideal, are wider in composition and to that extent considerably better than in former times It is perhaps worth mentioning too that university bodies in the oversea territories seem well content to leave much of the selection of men, even for senior posts, to committees appointed by the Inter-University Council and sitting in London

I have said nothing about a possible relationship between general practice in the United Kingdom and the proposals I have outlined There are two reasons for this this letter is already too long, and it would be better for questions concerning the general practice aspect of the N H S to be discussed by someone well versed in the subject

CYTOLOGICAL TESTS OF SEX

SIR,—I wish to plead for the utmost in caution and diplomacy in the use of such expressions as "female nuclei or male nuclei" and "genetic female or genetic male" when applying cytological tests of sex clinically Gonadal agenesis patients are feminine although their cells lack sex chromatin in the majority of cases Similarly a proportion of male pseudohermaphrodites are feminine, clinically and socially, although their body cells are of the male type A converse situation is encountered in some true hermaphrodites and in certain uncommon syndromes that are now being studied A well informed patient might be more disturbed than the circumstances warrant should he or she learn by a chance remark that the body cells are at variance with the obvious sexual anatomy Consequently, I would prefer to see used in the clinic such less committal expressions as "chromatin positive or chromatin negative"

The cytological tests of sex have important theoretical implications in the study of sex differentiation They also have a distinct diagnostic value in practice However, they should carry no weight beyond this, and I agree with Wilkins et al[1] who emphasise that the presence or absence of sex chromatin, in congenital errors of sex development, is a minor detail in the femaleness or maleness of the whole person It would be most regrettable if the advantages that accrue from having available a cytological test of sex were marred by placing an additional psychological burden on any patient who suffers from an abnormality in sex development

The recent applications of cytological tests of sex in clinical practice emphasise the necessity of fundamental cytological studies to establish what relation there is between the sex chromatin and the sex chromosomes The suggestion that the "female" sex chromatin is derived from heteropyknotic portions of two X chromosomes is only a plausible hypothesis that is based on indirect evidence[2] Should this hypothesis prove incorrect the cytological tests would retain their practical usefulness in differential diagnosis, but theoretical derivations might be greatly affected In particular, it is premature to equate female type nuclei with genetic femaleness or male-type nuclei with genetic maleness, as a generalisation in errors of sex development, for our present methods give no direct information concerning the genes that are concerned with sex determination and sex differentiation

DISORDERS OF CONTEMPORARY SOCIETY

SIR,—Professor Pickering (Dec 3) refers to one factor which we, as a profession, could do something to control

It has been emphasised that the tyranny of the kings and princes has been replaced by that of the organised groups Today antagonisms grow up between groups as they once did between potentates

In war we are, as it were, thrown into a bag and shaken up together This gives many opportunities for understanding the other man's point of view and welds us together But when war ceases the opportunities thus presented are again taken away

In the field of industrial medicine this is painfully apparent, for those in one occupational group perceive dimly, if at all, their dependence on other groups Thus the factory workers distrust "the City" and those in the City condemn, all too easily, the factory man The fact that both are in the same production team is scarcely known and the two groups never really meet. Yet agencies exist that could facilitate such meetings by which, surely, mental health would be improved. Is not much sickness in industry of emotional origin and does not a lot stem from the antagonisms between groups?

---

[1] Wilkins L, Grumbach, M M, Van Wyk, J J Shepard, T H, Papadatos C *Pediatrics* 1955, 16, 287

[2] Barr M L *In* Modern Trends in Obstetrics and Gynæcology Edited by Kenneth Bowes Second series London, 1955, chapter 7 p 123

The politicians seem to know little about the way in which the stresses mentioned arise and are aggravated. By grandiose planning they make things worse and expect, without reason, that an individual can easily attach his loyalty and affection to some immense organisation. Yet all civil and military experience shows how difficult this is. In health services they also make things worse by undue segregation of occupational groups in separate medical services. But we have often, when sick, one of the rare opportunities in a hospital or other institution to make unusual contacts which daily life denies us. At such times we can meet those in different walks of life.

Is it not then a mistaken policy to create special services for special groups, excluding others from these services? Does not this policy help to widen the rifts between one group and another?

I see no reason why those concerned with mental health should not take more positive steps to break down the antagonisms described. They need not talk politics to do this. As specialists in a field which baffles the layman we have a duty to help in this situation and, in doing so, to avoid jargon as Professor Pickering so rightly says.

Standardisation and uniformity, whatever politicians may say, are biologically impossible and the attempt to impose them can only be disastrous. Stimulation comes from diversity and from the same source should come a better understanding of our fellow men. Are we not members one of another?

Hitchin, Herts. G. C. PETHER.

ἐμοῦ θανάντος
EMOU THANANTOS

SIR,—According to the old Greek myth, the rebellious Prometheus stole the secret of fire from Heaven and was punished terribly by the eagle, servant of Zeus, but had to be acknowledged as the greatest benefactor of the human race. Modern men, successors of Prometheus, have discovered the secret of nuclear energy. Will they become destroyers of the world, or, by harnessing nuclear energy, will they become the greatest benefactors of mankind? Julian Huxley[1] likens their possible destructive activity to that of a cancer on the Earth.

This choice for good or evil reminds me of something that I wrote many years ago in a fanciful article on the Teleological Aspect of Cancer.[2] It was an imaginary conversation between two cells of a living human being. One cell was complaining of bad treatment, and said "he was determined to try the effect of undergoing a malignant neoplasic mutation." The other cell, arguing against such a step, said "that by undergoing such a mutation he would be destroying the body on which he lived." The answer was that "although he himself would doubtless be dead, his host would live long enough for the birth of hundreds of insurgent descendants,[3] especially in the metastases, and it would be his great great, great, grandchildren who would suffer and that one really could not be troubled by what would happen to them." Indeed there is an old Greek saying, quoted in the works of Euripides: "when I am dead (ἐμοῦ θανάντος) let the earth be dissolved in fire." This is what I call the *emou thanantos* way of looking at many an important subject.

Even now, one continually hears people saying: "Ah well, I don't want to waste my time thinking about that. I shall be dead long before. What will it really matter to me?" But civilised man should say: "The question *ought* to matter to us—whether the world will be destroyed by gangsters after our life or not." If civilised man does not concern himself with such things, can one expect the less civilised peoples in various parts of the world to bother themselves with such thoughts? And those peoples are rapidly gaining in world power and in numerical importance.

HYDROCORTISONE IN PAINFUL SHOULDER

SIR,—Dr. Cyriax (Dec. 31) fails to grasp the purport of my letter of Nov. 5: my aim was to point out that cervical spondylitis with nerve-root involvement is often associated with capsulo arthritis of the shoulder joint, and may be the fons et origo thereof; in such cases the lowered muscle tone and loss of support, which are demonstrable by electromyography, have resulted in undue strain being put upon the joint structures, which in time they come to resent.

Neither in the article to which he refers, nor in his *Textbook of Orthopædic Medicine*, do I find that Dr. Cyriax specifically refers to this clinical syndrome.

Sunderland. W. GRANT WAUGH.

ECLAMPSIA

SIR,—Dr. Schuurmans (Dec. 17) says that 17 years ago it was suggested that the high incidence of eclampsia in Australia might be due to the large quantity of meat consumed there. Surely Hamlin has disproved this fallacious view?

In Australia by means of a high protein diet he has caused eclampsia to disappear. On the other hand, as Hamlin has found that limiting the intake of carbohydrate prevents excessive gains of weight, and is followed by the disappearance of severe toxæmia and eclampsia, it is logical to conclude that heavy carbohydrate intake produces the dangerous and excessive gains of weight which are followed by toxæmia and eclampsia.

In any prolonged war eclampsia is apt to diminish or disappear. It happened in Germany in 1914–18. War leads to food shortage and rationing, and so prevents over-eating; reduced intake of food prevents any excessive gain of weight and so is followed by the disappearance of severe toxæmia and eclampsia; this in turn results in fewer toxæmia-produced stillbirths and premature births; and since, as I have shown (Nov. 5), toxæmia and eclampsia affect mothers who are producing boys more often than those who are producing girls, the babies whose lives are saved are more often boys than girls. By this means Nature is able, through producing a surplus of live male babies, to compensate for the male combatants who have died fighting in the war. Post-war male population increases are well known.

The disappearance of eclampsia in Holland during the late war was, I am confident, due, not to the quality of the food, but to its severely reduced quantity. With the end of the war, and an increase in the quantity of food, over-eating became possible and eclampsia reappeared.

The diet which is suggested by Dr. Schuurmans to prevent eclampsia is more likely to produce it, unless bread and potatoes are restricted.

In a region where the disease is fairly common, I have found that for each case of eclampsia there are about 20 cases of toxæmia severe enough to necessitate induction of labour. Using the frequency of this procedure as an index of severe toxæmia, it is possible to note the effect of diet on toxæmia, and indirectly on eclampsia. In the years 1947–51, without controlling weight, the frequency of inductions for toxæmia in my patients was 7.7% (52 out of 674, including 3 cases of eclampsia), while in 1952–55 it was 3.2% (23 out of 710, including 1 case of eclampsia). In the latter period, at first I attempted to control weight only with anorexigenic drugs, but later, owing to the results being inadequate, I also instructed patients to cut their bread and potato intake (i.e., those foods which Dr. Schuurmans is recommending), with improved results. Of the 23 patients who were "failures," 18 had had excessive weight gains (that is to say, my control of their weight was inadequate) while the other 5 patients consisted of 2 primiparæ who were initially hypertensive (essential hypertension) and 3 multiparæ with initial hypertension and histories of having had previous toxæmia (i e, patients who according to my theory had permanently retained a hostility to invading transplacental hormones) By the correct diet, eclampsia and severe toxæmia can nearly always be reduced in severity to little more than mild toxæmia "Many cases of mild toxæmia" that still occur probably include a considerable number of "aborted" severe toxæmias or eclampsias

Dr Schuurmans doubts my theory that mothers may react to the entry of fœtal hormones because, he says, these do not differ in any respect from those of the mother But this is not an established fact Steroid chemistry is complex enough in the adult, but it has never been studied, and could probably never be studied, properly in the fœtus Apart from the suspicion that the sex hormones of the fœtus are probably produced by the adrenal cortex, instead of by the ovary in the mother, it is quite impossible to prove the truth of Dr Schuurmans' incautious statement about the hormones of the unborn baby, though it may well be possible to disprove it

To predetermine the fœtal sex by biochemical means, it is essential for the fœtal sex hormones in the mother to differ from the maternal hormones, and for the presence or influence of the fœtal hormones to be detected I suggested in my article that it might be possible to predetermine sex before but not after, the onset of toxæmia, because entry of fœtal hormones into the mother would then be resisted This suggestion, if confirmed, should dispel Dr Schuurmans's doubts concerning the possibility of maternal reaction to fœtal hormones

Reading K D SALZMANN

EARLY DIAGNOSIS OF COMPRESSION OF THE SPINAL CORD

SIR,—I would like to congratulate Mr Rowbotham (Dec 10) on his efforts to encourage early diagnosis of neoplasms causing cord compression, and endorse his views on the disastrous results of late diagnosis Recently I have seen four such cases

One of these four patients had a ten month history and bilateral palsy of the fifth, sixth, seventh, and eighth cervical and first thoracic nerve roots, but no sensory changes He had been treated for cervical spondylosis At operation he had a pachymeningitis

The next patient had an eight month history and a bilateral palsy of the fifth, sixth, and seventh cervical nerve roots, with sensory changes, the plantar responses were flexor He also had been treated as a case of cervical spondylosis At operation a benign intramedullary tumour was removed, and he is doing well

The third patient had a four month history and a unilateral palsy of the seventh and eighth cervical and first thoracic nerve roots with sensory changes There were no radiographic changes in the cervical spine, and there was no evidence of a Pancoast tumour (which may cause this type of palsy), but further radiographic examination showed the seventh cervical vertebra collapsing and by this time a supraclavicular gland was palpable, which biopsy showed to be malignant

The fourth case was in a young adult who had a seven month history and a bilateral first sacral palsy, bladder symptoms, and sensory loss from the upper buttocks to the outer side of both feet, including the anal and perineal areas Operation disclosed a tumour of the cauda equina

Each of these cases had been diagnosed as a disc lesion

I would like to add six criteria which help towards early diagnosis of spinal tumours

1 A history of increasing and intractable segmental pain

2 Peripheral symptoms, starting distally and progressing proximally, in the upper limb

3 Sensory changes in more than one dermatome

4 Rapid increase in the palsy This is common with disc lesions, but then only one nerve root is affected If more than one nerve root is affected, then a spinal tumour should be suspected

5 Bilateral sensory or motor changes, especially if more than one segment is affected

6 The plantar response is unreliable, since the response may not be extensor until late in the course of the disease

London W 1 R BARBOR

INGUINAL HERNIORRHAPHY

SIR,—Mr Doran (Dec 24) argues that, since the conjoined tendon forms the lower border of an inelastic aponeurosis, the "primary fixed point" remains equidistant from the anterior superior iliac spines, and the distance of this point from umbilicus and pubic crest remains fixed, no "shutter action" of the conjoined tendon is possible While the clinical and experimental evidence adduced seems to support this hypothesis, the geometrical argument appears to be fallacious

In his fig 1 Mr Doran represents the "primary fixed point" as the point of intersection of the diagonals of a quadrilateral whose apices are the umbilicus, the anterior superior iliac spines, and the pubic crest Were this the case the argument would hold In fact, however, the geometrical representation of these points is an asymmetrical four sided pyramid, with the primary fixed point at the apex Theoretically this figure degenerates into a quadrilateral when all five points are co planar, and the apex of the pyramid becomes the point of intersection of the diagonals of the quadrilateral Even if this configuration were present in an individual it would only occur temporarily, since any change in intra abdominal tension would alter the position of the primary fixed point in the sagittal plane

Once it is appreciated that the correct representation of these points is a pyramid it may be seen from geometrical considerations that the primary fixed point is only "fixed" in the coronal plane In the sagittal plane it is able to occupy a wide range of positions without its relations to the other four points in the coronal plane being altered Normally the primary fixed point lies anteriorly to the three bony points and the umbilicus On increasing the intra abdominal pressure, as in coughing, it moves more anteriorly Bearing in mind that the tissues between the conjoined tendon and the primary fixed point are inelastic, if one accepts Mr Doran's hypothesis one would expect the conjoined tendon to become further separated from the inguinal ligament The experiments with radio opaque markers show that, in fact, the distance between the markers remains fixed

One is led to the inescapable conclusion that there must be some mechanism which prevents further separation, and that this mechanism can only be the shutter mechanism of the conjoined tendon I submit therefore that the argument against this action of the conjoined tendon is based on a too literal interpretation of the word "shutter" The fact that apposition to the inguinal ligament or, indeed, any movement does not take place is not a valid argument against its action in maintaining the integrity of the inguinal canal Failure of reparative operations based on this principle must be sought elsewhere

London W 11 J F ROBINSON

SIR,—Mr Doran, in his paper which was read to the Anatomical Society, understandably confined himself to anatomical facts

The value of his observations would be enhanced for surgeons if he would state what incidence of recurrent hernia, if any, was noted among the 12 cases in which the conjoined tendon and Poupart's ligament eventually parted company, and among the 25 cases in which these structures remained in apposition

The gratifying freedom from recurrence in my experience after operations similar to that performed in Mr Doran's series suggests that, even if the conjoined tendon and Poupart's ligament separate, they yet remain joined by a sheet of fibrous tissue strong enough to form an adequate posterior wall to the inguinal canal

When recurrence has followed suture of the conjoined tendon to Poupart's ligament after making a relaxing incision, this has usually been a direct hernia through the medial end of the posterior wall of the inguinal canal This has led me to pay particular attention to the placing of the most medial stitch exactly at the attachment of Poupart's ligament to the pubic spine

This "master stitch" by itself usually brings the conjoined tendon into close approximation with Poupart's ligament and minimises the strain on the more lateral sutures I use fine nylon for these and a stouter strand for the "master stitch" It would be of interest to know what suture material Mr Doran used in his cases

Edgware General Hospital FRANK FORTY

CENTRAL SOCIETY FOR CLINICAL RESEARCH

SIR,—Your account[1] of this society's meeting includes an abstract of the paper on Renal Manifestations of Primary Aldosteronism which we presented with Dr Gordon Farrell This abstract contains an error

The patients were studied during hydropenia or 'Pitressin' infusion and osmotic diuresis In this situation they excreted slightly hypotonic urine The defect in net water reabsorption, measured as a negative $T^{c}_{H_2O}$, differed from that of diabetes insipidus in that it was not as extensive and was *not corrected* by pitressin Removal of the tumour resulted in at least partial recovery of the function of urine concentration The preoperative defect is apparently a manifestation of renal tubular potassium depletion

The aim of the paper was to indicate that hypertension with excretion of dilute alkaline urine should bring to the clinician's mind the suspicion of aldosteronism, and perhaps lead, from these simple indications, to the uncovering of further cases of this unusual and interesting condition

ADRENAL HÆMORRHAGE

SIR,—I was interested by Dr Galpin's letter (Dec 17) The association of suprarenal hæmorrhage with an intracranial lesion has recently been commented on by Dr Buxton Hopkin (Nov 5) The presentation of his case as an exercise in the diagnosis of the "acute abdomen" prompts me to describe briefly a case I saw clinically and examined *post mortem*

A 43-year old man was admitted to Crumpsall Hospital on Dec 8, 1952, with left sided pleural effusion and underlying pulmonary collapse, which was confirmed radiographically Carcinoma of the bronchus was tentatively diagnosed The patient had had a chill four months previously, and a month later had complained of pain in the left side of the chest associated with breathlessness, slight cough, and weakness A week after admission the patient began to have severe constant pain in the epigastrium, penetrating through to the back, he did not vomit There was guarding but no tenderness and bowel sounds were absent His blood pressure was 140/80 mm Hg, having been 125/70 on admission A leaking perforation of a chronic duodenal ulcer was suspected in view of a history of ulcer pain, which had developed ten years previously after a fracture of the spine A policy of "wait-and see" was adopted Pain disappeared, bowel sounds became audible, and diarrhœa developed

Two days later, on Dec 17, the patient felt better, but suddenly his pulse rate rose to 128 per min, and his blood-pressure fell to 80/55, there were no signs of shock His blood pressure remained constant at this level, and he complained of weakness Addison's disease was suggested On Dec 30 the serum sodium level was 240 mg per 100 ml, and the serum chloride level 500 mg per 100 ml (as NaCl) The patient died quietly on Jan 4, his blood pressure never having risen above 80/60

Necropsy confirmed the presence of a carcinoma of the left main bronchus associated with bronchiectasis of the lung and chronic empyema The heart showed severe brown atrophy, and there was a chronic ulcer of the first part of the duodenum with no sign of perforation Both suprarenal glands had become shells of organised hæmorrhage, and it was impossible to say histologically whether there had been thrombosis or embolism Unlike the case recently reported by Mackenzie[1] no carcinoma was present in these glands

In many ways, both Dr Galpin's and my case are similar to the syndrome of "hæmorrhagic suprarenal infarction" reported by Keele and Keele[2] In their case there was repeated vomiting, severe persistent pain below the right costal margin with tenderness, and a remarkable absence of shock

I feel that if such a diagnosis is made during life noradrenaline by itself is insufficient, and full substitution therapy, and possibly chlorpromazine, are all worth giving, for otherwise the condition must be hopeless

Pathology Laboratory,
Withington Hospital,
Manchester

M LEVENE

ROSEOLA INFANTUM

SIR,—In your issue of Dec 3 Dr Letchner writes "Roseola infantum is a common infective disease, occurring nearly exclusively in the first 3 years of life, Complications are very rare, " I have observed in adults a very similar condition with occasional severe complications

In August and September, 1941, at No 12 General Hospital, Sarafand, Palestine, some fifty cases of what I termed (for want of a better name) "infectious roseola" occurred among the medical and nursing staff and patients Similar small outbreaks were noted in the surrounding district

Usually the onset was abrupt with frontal headache, pain on eye movement (a prominent feature in some cases), back ache, general muscular pains, and occasionally joint pains The fever was short lived and usually slight Three days was the usual duration, and 101°F the average highest temperature, though 104°F was recorded Anorexia and nausea, with coated tongue, were fairly common, and occasionally weakness of the legs, slight sore throat, and hyperalgesia of the skin occurred

The *rash* appeared on the 3rd to 8th day, but most commonly on the 4th or 5th day It lasted 5 to 7 days, and was of two types (1) a papulo erythematous, dusky, pink, discrete, morbilliform eruption, resembling measles, but not so blotchy, leading to no desquamation or subsequent staining, (2) less commonly, a much sparser and more discrete, pink, papular eruption The distribution of the two types was similar, affecting the following parts (in order of situation and density) (*a*) back, chest, upper arms, (*b*) forearms, abdomen, thighs, face and neck, legs, (*c*) hands and feet, palms, soft palate The eruption usually appeared a day or so after the temperature had become normal and was not accompanied by a secondary rise of fever There were no successive crops

The *glandular enlargement* appeared with the rash, though it was not seen in every case, and consisted of a generalised slight lymph gland enlargement without tenderness The epitrochlear glands were fairly commonly enlarged There was no splenic enlargement

The *blood picture*, in those cases that were examined, most usually included leucopenia (about 3000 white cells per c mm) with a relative lymphocytosis of 50%, in the first few days of the illness The great majority of cases cleared up completely and rapidly without sequelæ, although sometimes debility, anorexia, and nausea persisted for 10–14 days

The only serious complication was *encephalitis* and three cases of this, with a fourth possible one, were observed They were characterised by fever, headache, neck stiffness, positive Kernig's sign, mental change, and tremor, with no gross abnormalities in the cerebrospinal fluid (c s f) The fourth patient had fever, headache, and some mental confusion with no physical signs, and the c s f was not examined All recovered completely

I had the impression that *atypical cases* also occurred—e g, glandular enlargement without rash, a kind of prodromal

---

[1] *Lancet* 1955, ii, 1120

---

[1] Mackenzie D H *J Path Bact* 1955, 69 333
[2] Keele, D V, Keele, K D *Brit med J* 1942 ii 687

mottling without development of a true rash, or general symptoms without either rash or enlarged glands

The *Weil-Felix and Paul Bunnell reactions* were negative in all cases tested

From two cases in Tel Aviv, in which the practitioner concerned could obtain comparatively precise dates as to time of contact and removal therefrom, the *incubation period* appeared to be 4–5 days

Milian[1] under the heading Roseole Infectieuse, refers briefly to a somewhat similar condition which had previously been noted by Trousseau (roseole saisonnière), and Fournier (roseole simple), but I have not been able to examine the latter articles

I could arrive at no conclusion as to cause or method of spread, but arthropod vectors were most unlikely and the occurrence of encephalitis suggested that the condition might be due to a virus infection

Folkestone

F R FLETCHER

CANCER OF THE FEMALE BREAST

SIR,—The point made by Dr Holtzer (Dec 24) is important, and perhaps I should have explained fully how the rates were adjusted rather than make the bald statement "the five year survival-rates have been corrected for age"

The denominator used to calculate the corrected survival rate for any age group is not the total number of women that fall within that age group but the number expected to be alive at the end of the five year period, under the normal conditions of mortality Thus the 65–69 age-group contained 1250 women of whom 367 were alive five years later, but according to the current life table 1035 should have been alive

The crude five year survival is of course $\frac{367}{1250}$ or 29 4%,

but when corrected for age it is $\frac{367}{1035}$ or 35 4%

General Register Office
London, W C 2

A. MCKENZIE

NOR ANY DROP TO DRINK?

SIR,—Your article under this heading (Dec 17) covers almost all aspects of Civil Defence in the thermonuclear age I should like here to put forward only three points

(1) The Ministry of Housing and Local Government have had for some time arrangements for "mutual aid" for water undertakings, though as far as I am aware no full survey of potential water-supplies has been made—at least not in this area

(2) On the question of the contamination of water supplies by fission products I think that perhaps we (and you) may be too pessimistic, as the Atomic Energy Research Establishment have been into this already and have taken samples in various places to determine basic levels One supply in this area (from an underground working from which pitchblende was obtained many years ago) was found to have a degree of radio activity vastly higher than any other place in this country, yet the inhabitants are just as healthy as those near by who do not drink the same water There is also a place in Sweden where the water has a radioactivity 100 times greater even than that just mentioned, but there is no information that the people living there are not healthy

For reservoirs, owing to the relatively short half life of some at least of the most dangerous fission products, storage would help, while, where there are filters, using an alum floc and the actual physical scraping of the sand *surface would* remove more It is highly unlikely that there would *be any* electricity for a number of days, so pumps for water and sewage would not be working unless Diesel operated

In such circumstances it is obvious it would be criminal to waste a drop, and this should be impressed on the Fire Service, which under present arrangements seems to imagine that unlimited quantities of water will be available *to put out* fires The answer is of course that houses would have *to be* dynamited for fire breaks and the rest left to burn

(3) The teaching of "field hygiene," especially to sanitary inspectors, was recommended by the medical officers of health course at the Civil Defence Staff College as long ago as May, 1951 But no action has been taken by the appropriate departments

With regard to (1) and (2) I would refer you also to the contamination of the Wabash River after the historic "Trinity" test, and also to a paper by Tsuzuki[1]

Penzance

W K DUNSCOMBE

NEEDLE BIOPSY OF THE KIDNEY

SIR,—We were delighted with the conservative attitude of your editorial of Dec 10 My colleagues and I have done over 400 renal biopsies in the past few years No patient has died as a result of the procedure, the patient has died as a result of the procedure, the morbidity has been slight, and in no patient was surgical exploration necessary None the less, we believe that, for the time being at least the procedure should be done in special centres and only by those who have been trained in this technique

We were interested in several points raised by you

> You state that "several patients have already had as many as four successive biopsies, giving detailed information of progressive renal disease which could not have been obtained by other means This is not, however, an adequate justification for a potentially dangerous operation, and biopsy should be used only when the information it gives will be of direct advantage to the patient, and not merely a rather academic addition to medical knowledge"

This is a most important statement, for it emphasises again that the clinical investigator must be first a clinician, whose chief consideration is the care of the patient[2] As we have shown, in selected cases, serial biopsy of the kidney has provided data which could not have been obtained in any other way and which was of great value in the care and management of our patients and their illnesses The serially taken biopsies have incidentally provided new knowledge of the natural history of diseases which, as John Ryle taught us many years ago on the wards of Guy's Hospital,[3] is not "merely a rather academic addition to medical knowledge"

> Later you state "that in patients with the nephrotic syndrome therapeutic trial [of cortisone or corticotrophin] would give the same information [as renal biopsy] with less disturbance to the patient"

Unfortunately this is not true Without histological information the response to cortisone or corticotrophin is always unpredictable, this is hardly surprising if we recognise that "nephrotic syndrome" is but a syndrome with many underlying pathological causes When the nephrotic patient is first seen the clinician is faced with the problems of how to treat him, for how long, and whether to treat a second time This decision can be made with far more confidence if the underlying pathology is known In our experience, no good has been achieved in patients with severe glomerular lesions who have been treated with corticotrophin or steroid hormones And in some cases at least it is our opinion that their clinical condition has deteriorated greatly as a result of treatment with these hormones As far as "*disturbance to the patient*" is concerned, our patients who have *needed a* bone marrow or hepatic biopsy as well as a renal biopsy have told us they have been least disturbed by the latter *procedure. It* has also come as a surprise to us to find *that* a number of our female patients were disturbed less by renal biopsy than by catheterisation of their bladders

> You end by saying "There are other interesting possibilities, but it seems unlikely that renal biopsy will achieve the importance that liver biopsy is now assuming Many

ADRENAL HÆMORRHAGE

SIR,—I was interested by Dr Galpin's letter (Dec 17) The association of suprarenal hæmorrhage with an intracranial lesion has recently been commented on by Dr Buxton Hopkin (Nov 5) The presentation of his case as an exercise in the diagnosis of the "acute abdomen" prompts me to describe briefly a case I saw clinically and examined post mortem

A 43 year old man was admitted to Crumpsall Hospital on Dec 8, 1952, with left sided pleural effusion and underlying pulmonary collapse, which was confirmed radiographically Carcinoma of the bronchus was tentatively diagnosed The patient had had a chill four months previously, and a month later had complained of pain in the left side of the chest associated with breathlessness, slight cough, and weakness A week after admission the patient began to have severe constant pain in the epigastrium, penetrating through to the back, he did not vomit There was guarding but no tenderness and bowel sounds were absent His blood pressure was 140/80 mm Hg, having been 125/70 on admission A leaking perforation of a chronic duodenal ulcer was suspected in view of a history of ulcer pain, which had developed ten years previously after a fracture of the spine A policy of "wait and see" was adopted Pain disappeared, bowel sounds became audible, and diarrhœa developed

Two days later, on Dec 17, the patient felt better, but suddenly his pulse rate rose to 128 per min , and his blood pressure fell to 80/55, there were no signs of shock His blood pressure remained constant at this level, and he complained of weakness Addison's disease was suggested On Dec 30 the serum sodium level was 240 mg per 100 ml , and the serum chloride level 500 mg per 100 ml (as NaCl) The patient died quietly on Jan 4, his blood pressure never having risen above 80/60

Necropsy confirmed the presence of a carcinoma of the left main bronchus associated with bronchiectasis of the lung and chronic empyema The heart showed severe brown atrophy, and there was a chronic ulcer of the first part of the duodenum with no sign of perforation Both suprarenal glands had become shells of organised hæmorrhage, and it was impossible to say histologically whether there had been thrombosis or embolism Unlike the case recently reported by Mackenzie [1] no carcinoma was present in these glands

In many ways, both Dr Galpin's and my case are similar to the syndrome of "hæmorrhagic suprarenal infarction" reported by Keele and Keele [2] In their case there was repeated vomiting, severe persistent pain below the right costal margin with tenderness, and a remarkable absence of shock

I feel that if such a diagnosis is made during life noradrenaline by itself is insufficient, and full substitution therapy, and possibly chlorpromazine, are all worth giving, for otherwise the condition must be hopeless

M LEVENE

ROSEOLA INFANTUM

SIR,—In your issue of Dec 3 Dr Letchner writes "Roseola infantum is a common infective disease, occurring nearly exclusively in the first 3 years of life, Complications are very rare, " I have observed in adults a very similar condition with occasional severe complications

In August and September, 1941, at No 12 General Hospital, Sarafand, Palestine, some fifty cases of what I termed (*for want of a better name*) "infectious roseola" occurred among the medical and nursing staff and patients Similar small outbreaks were noted in the surrounding district

Usually the onset was abrupt with frontal headache, pain on eye movement (a prominent feature in some cases), backache, general muscular pains, and occasionally joint pains The fever was short-lived and usually slight Three days was the usual duration, and 101°F the average highest temperature, though 104°F was recorded Anorexia and nausea, with coated tongue, were fairly common, and occasionally weakness of the legs, slight sore throat, and hyperalgesia of the skin occurred

The *rash* appeared on the 3rd to 8th day, but most commonly on the 4th or 5th day It lasted 5 to 7 days, and was of two types (1) a papulo erythematous, dusky, pink, discrete, morbilliform eruption, resembling measles, but not so blotchy, leading to no desquamation or subsequent staining, (2) less commonly, a much sparser and more discrete, pink, papular eruption The distribution of the two types was similar, affecting the following parts (in order of situation and density) (*a*) back, chest, upper arms, (*b*) forearms, abdomen, thighs, face and neck, legs, (*c*) hands and feet, palms, soft palate The eruption usually appeared a day or so after the temperature had become normal and was not accompanied by a secondary rise of fever There were no successive crops

The *glandular enlargement* appeared with the rash, though it was not seen in every case, and consisted of a generalised slight lymph gland enlargement without tenderness The epitrochlear glands were fairly commonly enlarged There was no splenic enlargement

The *blood picture*, in those cases that were examined, most usually included leucopenia (about 3000 white cells per c mm) with a relative lymphocytosis of 50%, in the first few days of the illness The great majority of cases cleared up completely and rapidly without sequelæ, although sometimes debility, anorexia, and nausea persisted for 10–14 days

The only serious complication was *encephalitis* and three cases of this, with a fourth possible one, were observed They were characterised by fever, headache, neck stiffness, positive Kernig's sign, mental change, and tremor, with no gross abnormalities in the cerebrospinal fluid (C S F) The fourth patient had fever, headache, and some mental confusion with no physical signs, and the C S F was not examined All recovered completely

I had the impression that *atypical cases* also occurred—e g, glandular enlargement without rash, a kind of prodromal mottling without development of a true rash, or general symptoms without either rash or enlarged glands

---

[1] *Lancet*, 1955, ii, 1120

[1] Mackenzie D H *J Path Bact* 1955, 69 333

[2] Keele, D V Keele, K D *Brit med J* 1942, ii, 687

The *Weil-Felix and Paul-Bunnell reactions* were negative in all cases tested

From two cases in Tel Aviv, in which the practitioner concerned could obtain comparatively precise dates as to time of contact and removal therefrom, the *incubation period* appeared to be 4–5 days

Milian[1] under the heading Roseole Infectieuse, refers briefly to a somewhat similar condition which had previously been noted by Trousseau (roseole saisonniere), and Fournier (roseole simple), but I have not been able to examine the latter articles

I could arrive at nó conclusion as to cause or method of spread, but arthropod vectors were most unlikely and the occurrence of encephalitis suggested that the condition might be due to a virus infection

F R FLETCHER

Folkestone

CANCER OF THE FEMALE BREAST

SIR,—The point made by Dr Holtzer (Dec 24) is important and perhaps I should have explained fully how the rates were adjusted rather than make the bald statement "the five year survival rates have been corrected for age"

The denominator used to calculate the corrected survival rate for any age group is not the total number of women that fall within that age group but the number expected to be alive at the end of the five-year period, under the normal conditions of mortality Thus the 65–69 age-group contained 1250 women of whom 367 were alive five years later, but according to the current life table 1035 should have been alive

The crude five-year survival is of course $\frac{367}{1250}$ or 29 4%,

but when corrected for age it is $\frac{367}{1035}$ or 35 4%

London, W C 2

A. MCKENZIE

NOR ANY DROP TO DRINK?

SIR,—Your article under this heading (Dec 17) covers almost all aspects of Civil Defence in the thermonuclear age I should like here to put forward only three points

(1) The Ministry of Housing and Local Government have had for some time arrangements for "mutual aid" for water undertakings, though as far as I am aware no full survey of potential water-supplies has been made—at least not in this area.

(2) On the question of the contamination of water supplies by fission products I think that perhaps we (and you) may be too pessimistic, as the Atomic Energy Research Establishment have been into this already and have taken samples in various places to determine basic levels One supply in this area (from an underground working from which pitchblende was obtained many years ago) was found to have a degree of radioactivity vastly higher than any other place in this country, yet the inhabitants are just as healthy as those near by who do not drink the same water There is also a place in Sweden where the water has a radioactivity 100 times greater even than that just mentioned, but there is no information that the people living there are not healthy

For reservoirs, owing to the relatively short half-life of some at least of the most dangerous fission products, storage would help, while, where there are filters, using an alum floc and the actual physical scraping of the sand surface would remove more It is highly unlikely that there would be any electricity for a number of days, so pumps for water and sewage would not be working unless Diesel-operated

In such circumstances it is obvious it would be criminal to waste a drop, and this should be impressed on the Fire Service, which under present arrangements seems to imagine that unlimited quantities of water will be available to put out fires The answer is of course that houses would have to be dynamited for fire breaks and the rest left to burn.

(3) The teaching of "field hygiene," especially to sanitary inspectors, was recommended by the medical officers of health course at the Civil Defence Staff College as long ago as May, 1951 But no action has been taken by the appropriate departments

With regard to (1) and (2) I would refer you also to the contamination of the Wabash River after the historic "Trinity" test, and also to a paper by Tsuzuki[1]

W K DUNSCOMBE

Penzance

NEEDLE BIOPSY OF THE KIDNEY

SIR,—We were delighted with the conservative attitude of your editorial of Dec 10 My colleagues and I have done over 400 renal biopsies in the past few years No patient has died as a result of the procedure, the morbidity has been slight, and in no patient was surgical exploration necessary None the less, we believe that, for the time being at least the procedure should be done in special centres and only by those who have been trained in this technique

We were interested in several points raised by you

> You state that "several patients have already had as many as four successive biopsies, giving detailed information of progressive renal disease which could not have been obtained by other means This is not, however, an adequate justification for a potentially dangerous operation, and biopsy should be used only when the information it gives will be of direct advantage to the patient, and not merely a rather academic addition to medical knowledge"

This is a most important statement, for it emphasises again that the clinical investigator must be first a clinician, whose chief consideration is the care of the patient[2] As we have shown, in selected cases, serial biopsy of the kidney has provided data which could not have been obtained in any other way and which was of great value in the care and management of our patients and their illnesses The serially taken biopsies have incidentally provided new knowledge of the natural history of diseases which, as John Ryle taught us many years ago on the wards of Guy's Hospital,[3] is not "merely a rather academic addition to medical knowledge"

> Later you state "that in patients with the nephrotic syndrome therapeutic trial [of cortisone or corticotrophin] would give the same information [as renal biopsy] with less disturbance to the patient"

Unfortunately this is not true Without histological information the response to cortisone or corticotrophin is always unpredictable, this is hardly surprising if we recognise that "nephrotic syndrome" is but a syndrome with many underlying pathological causes When the nephrotic patient is first seen the clinician is faced with the problems of how to treat him, for how long, and whether to treat a second time This decision can be made with far more confidence if the underlying pathology is known In our experience, no good has been achieved in patients with severe glomerular lesions who have been treated with corticotrophin or steroid hormones And in some cases at least it is our opinion that their clinical condition has deteriorated greatly as a result of treatment with these hormones As far as "disturbance to the patient" is concerned, our patients who have needed a bone marrow or hepatic biopsy as well as a renal biopsy have told us they have been least disturbed by the latter procedure It has also come as a surprise to us to find that a number of our female patients were disturbed less by renal biopsy than by catheterisation of their bladders

> You end by saying "There are other interesting possibilities, but it seems unlikely that renal biopsy will achieve the importance that liver biopsy is now assuming Many

[3] Ryle J A The Natural History of Disease London, 1948

lives have been saved by liver biopsy in the differential diagnosis of prolonged jaundice, but accurate differential diagnosis of renal disease is rarely of such immediate and crucial importance "

We wonder whether this prognostication is based on personal and comparative experience in the use of needle biopsy in the care of patients suffering from either hepatic or renal disease

Our experience with hepatic biopsies goes back many years and is much more extensive than with renal biopsy To tell the truth, we are embarrassed to admit that we have saved lives with hepatic biopsies, but even this early in the game we will admit having cured some patients with renal disease as a result of biopsy of the kidney On the basis of our experience with both types of biopsies we suspect that biopsy of the kidney will be of greater potential value to patients with diseases involving the kidney than hepatic biopsy is to those with jaundice and other types of hepatic disorder As a matter of fact, we find less use today for hepatic biopsies than we did a few years ago This is to be expected because, *from hepatic biopsies*, we have learned so much of the natural history of the different diseases which produce cirrhosis or result in jaundice that we are now able to recognise them early and *clinically*

It is probable that few needle biopsies of the kidney will be necessary *twenty* years hence, *for by that time* clinical investigators will have sorted out, by renal biopsy, the early and *treatable* stages of the many diseases which produce the end stage kidney At present these are lumped together by physicians under the all inclusive "chronic glomerulonephritis"—the diagnosis of which is equivalent to a death sentence

ROBERT M KARK

THE FORGOTTEN PATIENT

SIR,—The letter (Dec 24) from the president and secretary, Friends of Menston Hospital, states that the findings of a *Daily Express* investigation "cannot be dismissed so airily as Dr Duncan (Nov 12) would have us think" I can ignore the rebuke from Mr Carter and Mr Cripps, but not their inaccuracy My protest of Nov 12 neither included nor implied reference to any newspaper *investigation or articles*

Severalls Hospital,
Colchester, Essex

A G DUNCAN

CERVICAL VERTIGO

SIR,—*I was interested in last week's article by* Dr Ryan and Dr Cope

They describe five cases of vertigo associated with cervical abnormalities and attribute the vertigo in each case to interference with the tonic neck reflexes In describing each case they state that the aural findings were negative What does this mean? If every ear tested was clinically normal and gave normal audiometric and caloric results, they *should state this* If audiometry and caloric testing were not done their observations on the ætiology of the vertigo are valueless

Evidence is accumulating rapidly that labyrinthine vertigo is linked closely with the autonomic nerve-supply *to the* vessels supplying the inner ear It would appear that interference with the cervical sympathetic chain might well have caused the vertigo in all five cases by causing a temporary *alteration in the blood* supply to one or both inner ears

The conception of "cervical vertigo" put forward by Dr Ryan and Dr Cope merely increases the present confusion on this subject, and in laying stress on the cervical abnormalities present may tend to prevent proper otological investigation of these cases in future

T J WILMOT

STREPTOKINASE IN TREATMENT OF INFLAMMATION

SIR,—Professor Dubos, in his account of the *Micro* environment of Inflammation,[1] has reviewed a new field to which he himself has made many significant contributions

The œdema fluid in inflamed areas contains large amounts of fibrin The deposition of fibrin in the tissue fluids and the formation of thrombi in the arteries, capillaries, veins, and lymphatics help to wall off the area of infection by aiding in the formation of a *limiting* membrane This defence curtain has been correctly regarded as a beneficial structure, and its preservation, in order to inhibit the spread of infection, has been considered a basic surgical necessity

The advent of streptokinase has produced *a change* in thought about the barrier The chemical nature of the limiting membrane might be changed by administration of streptokinase, for this *will indirectly cause lysis* of fibrin through activation of plasminogen to plasmin, which is the active lytic agent Such a change *would* be beneficial, since the antibacterial drugs, being borne by the blood, cannot pass through the limiting membrane *from without any more than can pathogenic bacteria* from within The inefficiency of the antibacterial drugs in the treatment of abscesses, walled off cellulitis, and similar infections is well recognised

'Varidase,' which contains streptokinase and streptodornase, has been used as the source of streptokinase, since a pure preparation of streptokinase has not yet been made [2] (The streptodornase content can here be disregarded) Varidase was dissolved in physiological saline so that the final concentration of streptokinase was 10,000 units per ml The solution must be stored in a refrigerator, and a fresh solution was made daily 5000 units of streptokinase in 0 5 ml of physiological saline was injected intramuscularly, usually in the gluteal area, twice daily for a total of six doses or more if necessary One of the antibacterial drugs must be given, either orally or parenterally, when streptokinase is injected intramuscularly in the treatment of infection and/or œdema A spreading infection may result from dissolution of the membrane if protection against the contained bacteria is not provided

In 64 patients with abscess, cellulitis, empyema, epididymitis, hæmarthrosis, thrombosed hæmorrhoids, orchitis secondary to mumps, sinusitis thrombophlebitis and œdema, 45 excellent and 15 good results were obtained The 4 poor results were in a patient with paraplegia and extensive decubitus ulcers which were resistant to all forms of treatment in 2 patients with peripheral arteriosclerotic vascular disease with gangrene, and in a patient with thrombosed hæmorrhoids who did not receive sufficient treatment

Of patients who were benefited the redness and œdema started to decrease in a few after several hours, and in all receded considerably by the end of two days In the patients with granulating wounds, healing was hastened by reduction of the surrounding induration Delay in healing was not seen in any of the patients Pain and tenderness at the site of injection, noted in about 60% of the patients, disappeared about twenty four to forty eight hours after the injections were stopped The pain and tenderness were probably due to the streptokinase in varidase, since they were not encountered in patients given streptodornase alone A granuloma at the site of injection was not seen in any of the patients A rise in temperature attributable to the streptokinase was noted in about 10% of the patients A significant change in the total and differential white blood cell counts and in the prothrombin time was not *found*, fibrinolysis, determined by the whole blood technique, was not observed, hæmorrhage, hæmatomas, and petechiæ were not seen, and chills, cyanosis, or *allergic responses were* not noted Administration of anti histamine drugs was not necessary

---

1 Dubos, R J *Lancet*, 1955 ii 1
2 Miller, J M Surmonte, J A Ginsberg M, Ablondi, I A *Maryland St med J* 1955, 4 188

To obtain good results from the intramuscular injection of streptokinase in the treatment of infection and œdema, the involved area must have an adequate circulation Because of the risk of hæmorrhage, streptokinase should not be given to patients with defects of the blood clotting mechanism

Fort Howard, Maryland, U S A
JOSEPH M MILLER

LIGNOCAINE

SIR,—Since lignocaine was introduced some six years ago there have been sporadic reports of toxic reactions, the latest being that by Mr Dutton in last week's issue

Recently, Lock and Greiss[1] have recorded a case of convulsions and death following the administration of 40 ml of 2% lignocaine ('Xylocaine') for pudendal block, which they regard as "a gross overdosage" Nevertheless, because of its many advantages over procaine, lignocaine is the agent of choice in obstetrical local anæsthesia, and it would be a pity if the occasional adverse report should deter obstetricians from employing this excellent drug

Having used lignocaine in many hundreds of cases over the past five years, I have sometimes noticed marked drowsiness during or soon after delivery, and at first welcomed this effect for its associated amnesia However, since observing an attack (fortunately transient) of pallor, twitching, and cyanosis after the injection of 60 ml of 1% lignocaine I have tended to use only the 0 5% solution, and like Mr Dutton I find 50 ml quite ample for pudendal block and perineal infiltration I should like to endorse Mr Dutton's plea for care in the use of this valuable agent, and for administration of the smallest effective amount in the lowest concentration possible

Pinner, Middlesex
J P O'DWYER

BLOOD-TRANSFUSION

SIR,—In your leading article last week you state "Hospitals that have no resident clinical pathologist should not undertake work in which transfusion is often needed" This suggestion is quite impracticable It is difficult enough, if not impossible, to maintain resident medical and surgical posts at their correct level in many non-teaching hospitals, let alone find resident clinical pathologists in the numbers which would be required

Blood-grouping and cross matching is a purely scientific technique which can be learned by any person with sufficient intelligence whether he has been trained in the art of medicine or not The classification of a case as a dangerous recipient depends almost entirely on information given by the clinicians on the request form A pathologist with duties at more than one hospital cannot possibly supervise individual tests, whether routine or emergency, and in practice the vast bulk of this work is done entirely by technicians Furthermore, experience shows that in reading difficult or doubtful agglutinations the opinion of the technician of a few years' experience is greatly superior to that of a doctor who has only been doing the job for a few months, indeed, such an opinion is frequently better than that of the pathologist in-charge who sees only occasional tests at irregular intervals

This is one aspect of the problem of the best use of man-power It must be pointed out that if technicians are not attracted to the hospitals because the salary-scales do not compare sufficiently favourably with those obtainable in other scientific appointments, the blood-transfusion service will be among the first to be the most seriously affected

Department of Pathology
Kingston General Hospital,
Hull
A J SHILLITOE

PULMONARY EMBOLISM

SIR,—In your leading article last week you cite the view that it is the first embolism that kills, and that the patient who survives has little to fear from later ones I am not clear whether this is intended to refer to postoperative cases only, of which it may be true, it is certainly sadly at variance with experience in medical, as opposed to surgical, practice I have recently reported,[1] in a different connection, three cases in which the warning emboli were misinterpreted as disease of heart or lungs, until a final one enabled the true sequence of events to be established by the pathologist at necropsy These are by no means unique, and an awareness of the possibility of premonitory non fatal embolism would, I am sure, save many lives It would be unfortunate if your words diminished our alertness in this respect

Although prophylactic division of veins may be, as you say, unjustified, the operation is, in my experience, the only effective therapeutic measure in those cases of recurrent pulmonary embolism from the legs that occur from time to time

London, W 1
P PETCH

PROTOPHRENIA

SIR,—In his attempt to demonstrate the rôle of emotional injury in the production of mental defect Dr Bourne (Dec 3) summarises observations on 154 severely defective children under 6 years of age who had been admitted to the Fountain Hospital during the previous two years It is surprising, however, to note *that*, whereas *138* of these children had an organic defect, only 16 belonged to the "residual" group classified by Tredgold as having the "simple variety of primary amentia," which in outpatients outweighs the organic defect For this unusually high proportion of "organic" cases there seem to be two reasons The first is that few parents of a normal-looking child below school age who can walk and can control his sphincter, will agree to have him certified as a mental defective and *sent to an institution* The second is that, with the existing shortage of institutional beds, normal-looking children without gross motor disability will not gain admission to hospital unless they show "socially intolerable" behaviour These two circumstances may *explain* why *(1) almost all Dr* Bourne's "residual" cases have feckless or otherwise unsuitable parents, and (2) these few "residual" cases show all "socially intolerable" behaviour disorders

Few would doubt that adverse environment tends to aggravate the clinical picture of mental defect by adding psychotic features to those of intellectual retardation They would even agree with Dr Bourne that psychotic traits of this kind are observed more often in children with normal appearances, for if a mentally defective child appears normal he is liable (and even more so) in the "good" home, to educational pressure, confronting him with incomprehensible and insoluble requests which would never be addressed to a defective-looking child It is to this educational pressure, in its manifold forms, that the handicapped child responds with growing withdrawal, sometimes terminating in complete autism

As Dr Creak (Dec 17) and Dr Dutton (Dec 17) indicate, however, cases of the "residual" kind may, after all, have organic disease, and I would go further and say that in fact *clinical* signs and symptoms of such disease can usually be *found in them* *During* the ten years I have worked on mental defect I have found such signs and symptoms in almost all the many hundreds of young imbecile children whom I have examined and observed They are to be found both in those presenting obvious symptoms of organic disease and in those presenting none Apart from disturbances in simple reflex patterns—such as deficient oculomotor response on visual stimulation, loss or weakness of the pupillary light reflex, inability of convergence, and absent startle reflex on sudden loud sounds—one finds a considerable number of functional disorders which, if they were seen in adults, every neurologist would regard as infallible symptoms of localised brain impairment I have elsewhere described in detail four different syndromes, which I have found singly or in combination in all children with intelligence quotients between 30 and 50,[1] and in most children in the moron range [2] These disabilities (visuo-somatic, auditory-somatic, visuo autonomic, and auditory-autonomic) probably originate in disintegration of exteroceptor (visual, auditory) impulses and either proprioceptor or interoceptor impulses Such disintegration may result from metabolic errors as well as from structural lesions, affecting visual or auditory pathways anywhere in their course If the pathological process is confined to these perceptual pathways, and if it is not severe enough to cause total central blindness or deafness, the neurological syndromes may be overlooked and the child may be said to have no organic disease If mentally handicapped children were examined with the same precision as adults with suspected organic brain disease, I am sure that the organic basis of severe mental (i e , cognitive) defect could no longer be doubted Only the recognition and diagnosis of the *special* organic nature of a child's mental handicap will give us the understanding and the insight necessary for devising special medico educational methods to compensate for the weakened or lacking perceptual modalities

THYROID CANCER AFTER RADIOTHERAPY

SIR,—In the excellent annotation in your issue of Dec 17 you remark that a survey of the relationship between X-ray treatment in infancy and the development of thyroid cancer seems to be called for

I recently agreed to join with Dr Theodore Winship, of Washington, and Mr Frank Rundle, of Sydney, in carrying out such a survey, and I would be very grateful if particulars of any cases of thyroid cancer in children under fifteen years of age could be sent to me at New End Hospital, London, N W 3

London, W 1

RAYMOND GREENE

X RAYS FROM TELEVISION SETS

SIR,—In view of research work now going forward and of our knowledge of the effects of radiation upon tissues, it seems appropriate to raise the question of whether the great increase of television-viewing in the public generally does not bear some relation to the rather startling increase in the incidence of leukæmia and lung carcinoma Every television set contains a cathode ray tube and every such tube emits radiation when "on" I know of no investigation which has been undertaken on the effects on tissues of whatever radiations such tubes emit, but I see no reason to suppose they differ from those emitted by an X-ray cathode tube Very small quantities of radiation over a long period are, I believe, carcinogenic If there is the slightest possibility that the emanations from the average television tube are carcinogenic, then the matter calls for the most immediate and complete investigation

London, N W 3

N CHISHOLM

*** We understand that Dr Chisholm's important question can be answered reassuringly—for television-viewers at any rate The television sets at present in general use are of low voltage, and the manufacturers see to it that the tube is screened in such a way that no significant quantity of radiation escapes But technicians and others who regularly handle sets with the screening removed may be repeatedly exposed to low-energy X rays, and the risk they run in this way deserves close attention —ED L

FIRST-AID TREATMENT OF THE UNCONSCIOUS PATIENT

SIR,—Recently some first aid textbooks have been criticised for their recommended treatment of insensibility, and the neurosurgeons have very kindly advised as to improvement in this treatment The St John Ambulance Association has accepted their ruling and has issued to its members a supplement to their textbook *First Aid to the Injured* giving the revised treatment

The essential point made is the great danger of pneumonia due to the inhalation of secretions, blood, or vomit into the respiratory passages, and the treatment now includes the following rules

1 If breathing is obstructed in any way by blood, secretions, or vomited matter, lay the patient on his side in the three quarters prone position (half-way between side and face down position) and ensure that the throat and lungs are free from obstruction

2 Support the patient in this position with a pad in front of the chest If no pad is available draw up the patient's upper knee

3 If there is still any tendency to choke, the patient should be placed in the full prone position with the head lower than the feet and turned to one side

4 Keep a continuous and careful watch on the patient

STAFFING LABORATORIES

SIR,—I am glad that other pathologists beside me are concerned at the proposed new gradings in laboratories After two years' bitter labour the Whitley Council has delivered itself of a ridiculous mouse

I think that it was in 1946 that laboratory technicians last had a reasonable salary award There have since been minor adjustments, but I doubt whether the salaries of senior technicians especially have kept pace with their responsibilities and standards

If the new gradings are to be forced upon us, we, as pathologists, will have to bear the opprobrium of their imposition on individuals Although our advice in this matter appears to have been ignored the technicians who will suffer will blame us The great danger is that the new gradings would tend to produce in time a kind of second class senior technician who works in a second class laboratory In my opinion this idea cannot be too strongly condemned It would certainly not benefit either patients or staff

May I make an earnest plea to the Whitley Council to think again and to try and achieve a more generally acceptable result ?

Group Pathological Laboratory,
Lakin Road, Warwick

A P PRIOR

SIR,—Dr Taylor (Dec 24) is rightly concerned about the difficulty of staffing laboratories in the smaller hospitals, but he is on debatable ground when he says without qualification "Remuneration in the higher grades of technology should depend on individual merit" All will agree that it is proper that the most meritorious candidate should be appointed to a vacant post, but merit awards to holders of posts have not been such a success in hospital medical staffing that we should lightly approve an extension of the principle to laboratory staffs

The only equitable method of rewarding specific senior posts is to grade them according to the technical standard necessary for the work to be carried out efficiently, and this must depend on the technical skill called for by the work involved, and also the amount of responsibility entailed in the supervision of other technologists and the training of students and juniors—in short the "rate for the job," arrived at after consideration of all aspects of the case by persons, including the pathologist-in-charge, whose experience qualifies them to express an informed opinion

---

[1] Gellner L *Biology* 1951 16 130, and unpublished papers
[2] Gellner L *Spec Sch. J* 1955, 44, 12

When this had been done, a state would develop in which the more able men would be stimulated to apply for the higher-grade senior-technologist posts and would be at an advantage as candidates for such posts by reason of their superior experience and ability, while the less outstanding men would be absorbed into the less responsible posts, and would not have to compete for these against candidates of outstanding merit, who might be tempted to apply if the remuneration depended on the successful candidate's individual merit rather than on the nature of the work

CHILDREN IN HOSPITAL

Sir,—It was pleasant to read the account by Professor Illingworth and Dr Holt (Dec 17) of the kind and sensible régime at the Sheffield Children's Hospital

Their description of the all too common outbursts of rage and grief in child patients, following a visit by a parent, will be familiar to all who have worked in a children's ward These emotional cataclysms tend to be so harrowing in the case of younger children that, on this score alone, it might be difficult to persuade an observer who was unversed in the subtleties of child psychology that the encouragement of frequent visiting was anything more than an act of faith

The ultimate value of frequent visiting cannot be assessed simply by observing children and parents during a period of inpatient care I would urge Professor Illingworth and his colleagues to extend their valuable work to include the study of a child's behaviour before and after his hospital stay A controlled series could be obtained from the study of children who have the misfortune to be admitted to those few remaining hospitals where visiting is restricted or forbidden In surveys of this nature one cannot help believing that the assistance of a children's psychologist and psychiatrist would materially help the pædiatricians However well developed the sense of responsibility may be in the latter, without a psychological training it is difficult to describe, let alone interpret, any child's behaviour

HORDER MEMORIAL TRUST

Sir,—By the death of Lord Horder—who would have been 85 this month—the medical profession and the public have lost a very great doctor His former house-physicians at St Barthomomew's Hospital believe that there are many of his colleagues and former pupils, patients and friends, and those interested in the many activities to which he gave his support, who would like to contribute to a fitting memorial

With this object in view, his former house-physicians are asking for funds to inaugurate the Horder Memorial Trust, which has the approval of his family and the support of the Royal College of Physicians and of the Treasurer and Governors of the former voluntary hospital of St Bartholomew with which Lord Horder was so long associated The College and Governors have agreed to act jointly as trustees

It is proposed to found a travelling fellowship or professorship in clinical medicine—the science of healing at the bedside—for members of the medical profession, and if money permits to endow a lectureship in this subject at St Bartholomew's Hospital Throughout his long life, both as practitioner and teacher, Lord Horder always emphasised that a doctor's most important work is done at the bedside of his sick patient, and it is felt that a Trust of this nature will best serve to keep his memory alive, and will be of lasting benefit to the profession and therefore to the public also

Cheques, &c, should be made payable to the Horder Memorial Trust and sent to Sir George Aylwen, Bt, c/o St Bartholomew's Hospital, London, E C 1

Obituary

RENÉ LERICHE

MD, Hon FRCS, Hon FRCSE

Professor Leriche died at his Mediterranean villa at Cassis on Dec 29

Born in 1879, he received his education at the University of Lyons, and throughout his long life Lyons and its medical school retained the first place in his loyalties In his early years his surgical interests were wide His Thesis in 1906 was on resection of the stomach for carcinoma, and in 1909 he published with Poncet two volumes on surgical tuberculosis During his service with the army in the war of 1914–18 he became interested in fractures, and wrote discerningly on their treatment During this period also he began that study of vascular conditions which was to be the absorbing interest of his life After the war he practised in Lyons until 1924, when he was appointed professor of clinical surgery in the University of Strasbourg

His inaugural lecture at Strasbourg set the pattern for all his many and important contributions to the literature of surgery He had watched uneasily a tendency to overestimate the value of operative techniques, and in this address on "Physiological Surgery" he elaborated his own view that a patient must be studied as a whole, with the particular object of restoring function to diseased parts In formulating this approach—at the time somewhat unorthodox—he had been influenced by the writings of Claude Bernard, and to the end of his life this influence was to permeate and pervade his practice, and his papers and books

[Blanc & Demilly Lyons

During the fourteen years Leriche was in charge of *Clinique Chirurgicale* "A" in Strasbourg, he had always a number of pupils drawn from all over the world, many of whom now occupy important academic positions in their own countries It was a period of active and productive research, chiefly upon problems relating to the circulation, conducted both in his wards and in the experimental laboratory

Leriche was wholly disinterested in putting at the disposal of his staff both his vast clinical material and the profusion of ideas for research born in his fertile brain To his great natural resources of mind he added intellectual liberalism and receptiveness, the latter fed by frequent visits to surgical centres in Europe and the Americas He rapidly became a national figure, receiving all the honours his professional colleagues in France could bestow upon him, and also an international figure in his own right and in virtue of the dissemination by his disciples of his views and practice

In 1937 he accepted the position of Professeur au Collège de France Although this is the premier chair in France, it has the great disadvantage that the professor is not provided with clinical facilities in any teaching hospital in Paris, for the remainder of his active years Leriche's clinical work was private, and was done in his consulting rooms and in the American Hospital at Neuilly Each year the professor must deliver and publish a course of lectures Leriche's first volume was the well known "Surgery of Pain" a physiological essay in the Hunterian tradition In his next book he returned to an earlier interest, the physiology and pathology of bone The war interrupted these courses After it, his lectures dealt with vascular problems and, steadfast in his conviction regarding the correct approach to surgery, the title of each volume began with the words "Physiologie Pathologique " Each volume until the last in *La Philosophie de la Chirurgie* (1951) he reaffirmed his original concept of surgical practice, and recorded critically the modifications his own opinions had undergone in the light of his experiences in Strasbourg and Paris He was now an older statesman France had rewarded him by electing him to the Institute in the Academy of Sciences, he was the moving spirit (and a past president) of the International Society of Surgery, and he travelled widely both to lecture on surgical topics and to give advice on academic matters Two years ago he had an illness which curtailed many of these activities

In the operating theatre Leriche was deft without ever striving for the spectacular, always on the watch for some immediate problem in hominal physiology a friend described him as a peripatetic "why?" He was a superb expositor, clear and logical, it has been said that one did not require to know a word of French to follow what he was saying At the council table his disinterestedness and sincerity often rescued a discursive discussion—even an argument—from foundering, in a short speech in which he would unerringly go to the root of the matter at issue His interests in life were catholic He was a voracious reader and his apartment in Paris was full of objects of art, often the work of his grateful patients

Leriche was a good friend to this country and to its surgeons, who were always assured of a warm welcome He was an honorary fellow of the Royal College of Surgeons of England, of the Royal College of Surgeons of Edinburgh, and of the Royal Society of Medicine And in 1939 he was awarded the Lister medal, one of the most prized of his many distinctions

This memoir would be incomplete without some mention of the part played in his life by his wife, who watched over him with the most loving care, conserved—so far as was in her power—his exuberant energy, and delighted to share with him a gracious hospitality To her, as was inevitable, he dedicated his "Philosophy of Surgery"

A great leader, and one hard to replace, has passed from the world of surgery A suitable epitaph perhaps would be "L'homme est toujours plus grand que le chirurgien"

S A writes

I am glad he died at Cassis which he loved He had a house there among the rocks and pines of this small and sunny harbour Here he grew his own vines, and he was proud to offer his own wine to favoured friends in Paris

A characteristic picture of him would be at one of his clinics before 8 o'clock in the morning He would arrive at high speed in a small motor car, quite often on the wrong side of the road, or looking backwards and talking to a passenger He would bounce out of his car, and be half way up the corridor, with his assistants running behind trying to catch what he was saying He was small and round, gay and lively He had very bright intelligent eyes which twinkled over the tops of his half rimmed glasses He wore a plain grey suit and spotted bow tie, and was surprised that people in London knew he was French although he wore a suit of English worsted He was always interested in everything, full of ideas and energy In teaching he preferred to answer questions by posing others and getting one to supply one's own answer, often with much teasing He was a very eloquent lecturer, both in French and in English, but had in recent years refused to speak English after hearing himself speak on a recording a friend had made of one of his lectures in London

He never failed to stress the importance of honesty, and clarity, in writing notes, or research, and he liked statements to be put down plainly He thought diagrams and graphs were over emphasised, and ' appeal to the eye, not the intellect " By his precept he encouraged an inquiring attitude of mind It was a great privilege to have worked for a man who, by his work, his writings, and his personality, revealed himself as truly great

MALCOLM WATSON

Kt, M D, LL D Glasg, Hon F R F P S, D P H

Sir Malcolm Watson, who died at the age of 82 on Dec 28, was one of the outstanding characters of tropical hygiene during the past half-century He had been a pioneer in the control of malaria and for long was pre-eminent in its practice

[Press Portrait Bureau

He was already mature when he went to the Malayan Medical Service in 1901, being aged 27, having the M B Glasg and D P H, and having travelled as a ship's surgeon Ten years later his name was known throughout the world He found Malaya in a very critical condition on the one hand there was the promise of flowing prosperity from the wide expansion of the rubber industry, and on the other the threat of ruin from the devastating malaria epidemics which decimated labour forces and might well have brought the expansion to an end The transmission of malaria by mosquitoes had recently been demonstrated by Ross, but there was no practical experience of its control Watson set out at once to gain that experience and he set out with an ingenuity which has ever since remained unrivalled Almost alone he did not allow the aetiological discovery of Ross to blind him to the great fund of epidemiological knowledge which preceded it He saw malaria as occurring in certain types of surroundings whether of forest, brackish waters, clear streams, or other characteristics, the influence of which was explicable in terms of Ross's discovery though the surroundings remained the fundamental cause He developed techniques for modifying the surroundings or alternatively of recognising their danger and moving villages to safer areas He acquired no mean knowledge of civil engineering, working out mechanisms of tide control and a variety of forms of drainage By this breadth of outlook and combination of knowledge he whisked malaria away from place after place, turning literal death-traps into healthy sites The new Port Swettenham, on which work had been abandoned and which he sanitated by tidal control, was one of his earliest triumphs, to be repeated in different forms in many other places The peril which had threatened Malaya's prosperity was removed and that country became an outstanding example to the world, up to the time of the Japanese occupation, by the application of Malcolm Watson's principles This precedence over others was no mere temporary phase, for Malaya remained consistently twenty years ahead in this respect

He left government service and settled into private and consultant practice in Malaya in 1907, being called in to advise on many developments of industrial, municipal, and general natures, including the sanitation of Singapore in 1911 and the Perak River Hydro electric Scheme—the success of which gave him particular pleasure His success was generally acclaimed he received the gold medal of the Rubber Growers' Association in 1911, he was knighted and elected LL D of Glasgow University in 1921, received the Stewart prize of the British Medical Association in 1927, the William Jones gold medal of the Asiatic Society of Bengal in 1928, the Mary Kingsley medal of the Liverpool School of Tropical Medicine, in 1934, and the Albert medal of the Royal Society of Arts in 1939

In 1928 he left Malaya to become director of the malaria department of the Ross Institute, under the director-in-chief, Sir Ronald Ross, whom he succeeded in 1933, remaining in the post until his retirement in 1942 In these posts he set out to extend to other parts of the world the principles he had developed in Malaya, his first attempts were in Ceylon and India where he established a branch of the institute, the work of which showed that the principles were transferable though the techniques needed to be modified to local conditions His great interest lay in Africa and particularly in the Rhodesias, where a malaria-free settlement was built up in the Copper Belt under his advice, and he visited and advised in many other places in Africa, Europe, and the Americas He was a great believer in the benefits which industrial development could bring to the tropics and set himself to further them by advising industry on health matters and training its employees

Despite his success there was always controversy about Watson he did not conform to the patterns or practise many of the techniques which seemed to be dictated by the new scientific age, but again and again he achieved brilliant success where others could not Controversy raged round the question " Why ? " The answer lay in his combination of a general epidemiological approach with the narrower entomological approach which most people followed He had a great sense of fun, he enjoyed every minute of his work, he enjoyed his triumphs, his controversies, and even his failures because they always taught him something which would bring success another time He had in fact a very full life

He was married twice in 1900 to Jean Alice Gray who died in 1935, by whom he had three sons, and in 1938 to Constance Evelyn Loring by whom he had one daughter

G M

HENRY PRATT NEWSHOLME

M A, D M Oxfd, B Sc Lond, F R C P

For fifty years and more, the name of Newsholme has held an honoured place in the public-health service To the family tradition which his uncle Sir Arthur Newsholme began to establish in the '90s, Henry Newsholme, as medical officer of health and professor of public health in Birmingham, steadily added his own individual contribution

He was the son of the Rev B Pratt Newsholme, of Secunderabad, India, and he was educated at Brighton Grammar School and Balliol College, Oxford As a student he had a brilliant career, and in 1907 he took a first-class in the natural science school at Oxford and graduated B SC Lond with first-class honours He continued his medical studies at St Thomas's Hospital, qualifying in 1910 After holding house-appointments there he was in 1911 appointed an assistant school medical officer under the London County Council Later he held appointments at Brighton and Southend-on-Sea, and under the Surrey County Council During the 1914–18 war he served with the R A M C in France and Italy In 1915 he took his M D

After the war he was appointed M O H for the North Riding of Yorkshire, and in 1923 for Croydon In 1927 he succeeded Sir John Robertson at Birmingham and in the same year he was elected F R C P

At Birmingham Newsholme continued with outstanding success the development of the public-health services which Robertson had so soundly established *Perhaps* the most notable achievement of his years of office was the collaboration, without fusion, of the public-health and school medical services which had grown up separately His factual annual reports, each written as an essay in the best English style, won wide recognition He was able to record a state of health in which the city could justly take pride For years, despite unfavourable local circumstances, the infant-mortality rate, for instance, was below that for England and Wales But Newsholme also made important contributions to the theory of public health He read widely, as his bookshelves even in his office showed. In his own writings his religious and philosophical outlook was applied to his professional preoccupations and in 1929 he published *Health, Disease and Integration*, in 1933 *Evolution and Redemption*, in 1937 *Christian Ethics and Social Science*, and in 1951 *Matter, Man and Miracle*

In 1939 he and his wife were received into the Roman Catholic Church Of this important side of his life G A writes "Newsholme had been brought up in a religious household and his life was guided by his own firm faith and an essential spirituality which showed itself in a cheerful readiness to help others in times of trouble, sorrow, or crisis"

Another colleague who spent the troubled war years with him at Birmingham, recalls how he insisted on sharing to the full the war-time dangers and responsibilities of the health department

"For five years he shared equally with two junior medical members of his staff the exacting Civil Defence duties at central control This meant sleeping at the Council House each night for one week out of three

"He had a great deal of human understanding and was at all times courteous and kind But he was excessively shy and retiring by nature and I had the impression that, because of this, he was not always completely at ease in his position as head of a large and important public health department There was nothing of the 'showman' about him and he preferred to travel third class rather than first, and to walk or go by public transport rather than in a corporation chauffeur driven car"

From 1937 to 1941 Newsholme also held the chair of hygiene and public health He retired from his civic appointment five years ago, and he died on Dec 21 at the age of 70 His widow survives him with five children

OCTAVIA MARGARET SOPHIA LEWIN

M.B Lond

Dr Octavia Lewin, who died in London on Dec 27, graduated in medicine some sixty years ago She leaves a long record of independent but practical work Within the profession she will be chiefly remembered for her views on nasal hygiene and correct breathing As a member of convocation of London University, a school manager of the London County Council, and a governor of Bedford College, she also did much for education

She was born at Ware, the daughter of Spencer Robert Lewin, and was brought up in Wimpole Street She was educated at Queen's College, London, Girton College, Cambridge, and the Royal Free Hospital After qualifying in 1896 she held house-appointments there Her interest in diseases of the ear, nose, and throat led her to take a clinical assistantship at the Central London Throat and Ear Hospital. Later she was appointed rhinologist to the London County Council

During the 1914–18 war she worked in French hospitals and later as aural surgeon at the Endell Street Military Hospital When she gave up her work with the London County Council she continued to teach her methods of nasal hygiene and breathing exercises at the Westminster Health Centre, to which she was medical adviser She also wrote many articles and letters to the press describing her methods She was a member of the British Homœopathic Society and in 1945 she was elected a member of the Faculty of Homœopathy

L N writes

Octavia Lewin was a member of a large family who were left motherless when she was three years of age She early learned to be independent and fearless, and she retained these characteristics all her life When working as throat and ear specialist for the L C C she was convinced that lessons in breathing correctly should be given before tonsil and adenoid operation instead of after, as then practised She sacrificed a lucrative appointment rather than give up her pioneering method, which she taught at free clinics connected with the Westminster Health Society She insisted on only air being allowed into the nasal passages and deprecated all douching and syringing with liquids She taught people how to sneeze correctly, so that the expiratory blast blew away the excess mucus secreted in catarrh of nasal passages This was followed by voluntary blowing with mouth shut and head well down "Shut your mouth and save your life" was one of her repeated admonitions She invented all sorts of methods to train children to keep their mouth shut instead of being what she called "gapers"

Her many other interests kept her always young in mind and she was a storehouse of all sorts of original ideas in the home Her unfailing kindness and love for children was always practical She was a rare character and beloved by many

Mr L V. CARGILL

Prof Arnold Sorsby writes

"Lionel Vernon Cargill was associated with the Royal Eye Hospital for some fifty-five years In the early years he brought to it a keen and searching mind and superb technical knowledge and skill In the later years he was the elder statesman, guiding the hospital through a difficult period, increasing its bed complement from some 50 to 130, and initiating the research chair in ophthalmology at the hospital and the Royal College of Surgeons In all these activities he was the upright man of clear and decisive action

"His long life extended over the Victorian and Edwardian periods, and the turbulent years of two world wars Professionally he saw the transformation of ophthalmology from a minor branch of general surgery into an independent and significant specialty, and in this transformation he played his part, as is shown by his early publications and his services as ophthalmic surgeon to several general hospitals His work for the Society of Apothecaries and at King's College School, Wimbledon, were as valued and as disinterested as his more strictly professional activities"

Prof T B DAVIE

Two of Dr Davie's South African colleagues write

"His enthusiasm, energy, determination, and courage had made him a leading figure in academic affairs in South Africa He was one of those exceptional men who really enjoyed committee work The reasons were obvious to all who served with him his clarity of vision allowed him to crystallise for others the most complex administrative problems, and from his insight flowed solutions which gave him satisfaction, and which were invaluable to the university In the South African Council for Scientific and Industrial Research he served as a member of the council and as chairman of its medical and dental research committee It is not insignificant that during his term of office there was a steady increase in the output of medical research sponsored by the C S I R As member of the National Council for Social Research he was able to play his part in the development of research in fields other than that of science Since the recent establishment of the university advisory committee to the Minister of Education, Arts, and Science, Dr Davie had served on it as representative of the committee of university principals, and for this important position the South African universities could have chosen no better delegate He was also a trustee of the Max Sonnenberg University Trust, the Abe Bailey Trust, and the Isaac Ochberg Education Fund, and he was member of the governing councils of several public institutions and of many scholarship committees Through all this work and through his public statements he soon became known as a man who fought fearlessly for the principles he considered right Foremost among these he ranked the principles of academic freedom of universities, a freedom which he considered fundamental in a civilised world

"Despite his eminence he remained approachable by all He was always ready to listen to their problems and to give his guidance to members of his staff or to students In addition to his many official duties he found time for innumerable public engagements He was keenly interested in South Africa and its affairs, its history, its people, its flora and fauna Even his stamp collection had a South African bias

"Throughout his busy life he never forgot that he was a doctor' His medical school and medical research benefited greatly from his counsel, and he retained an interest in the affairs of the medical profession, being a strong advocate of the College of Physicians and Surgeons now being established in South Africa It was often said that he did the work of three men This is hardly an overstatement, yet for years he had been afflicted with arthritis which but for his indomitable spirit would have been incapacitating In part this achievement was due to the help he received from his wife The gap he leaves will be difficult to fill, but the example he set will remain vivid and living for many years to come"

S B, *who was one of his students, writes*

"Clarity, enthusiasm, and a robust humour were Davie's characteristics as a teacher He was the best I have known, and one of the best men It is easy for a teacher to display his knowledge and wit at the expense of a student, but though I saw Davie have a hundred opportunities of this kind, I never saw him take one Himself seemingly an extrovert, he seemed to have an intuitive knowledge of the minds and souls of others—springing perhaps from his most endearing quality, an ebullient and childlike innocence He gave us his knowledge and he made us laugh with him I once made a ludicrous, but unfortunate, mistake in a pathology viva For a moment my fate seemed to hang in the balance The external examiner looked grave Then Professor Davie threw back his head and burst into enormous laughter, and brushing the mistake aside, the three of us went happily on He knew and I knew that I was not going to let him down again

"After the war I had occasion to ask his help in a small personal matter I did not think he would remember one out of the thousands of students he had known, and was he not, in any case, head of the University of Cape Town? But he did remember me, and he did help me, though then an ill man, grappling with issues a thousand times more important than my small business Like many teachers, he inspired respect in his students, but much more he inspired affection The keynote of his life was youth he looked young, he thought young, and it was to the young that he devoted most of his days I am sure that many will remember all their lives this noble man, whose death has saddened as much as his life rejoiced us"

Notes and News

SHORTAGE OF MENTAL NURSES

ADDRESSING a meeting in Shrewsbury last month, Dr M J Brookes drew attention to the acute shortage of nurses in Shelton Hospital, of which he is the medical superintendent This hospital, built 112 years ago to accommodate 176 patients, has been expanded, and its present statutory accommodation is for approximately 750 patients Nevertheless, over 1000 patients are in residence There are only 67 full time nurses and 48 part-time nurses—i e, the equivalent of about 91 full time nursing staff—whereas the ideal establishment would be 270 This means, in practice, that 3-4 nurses look after 50-60 patients, whereas the ideal figure would be 1 nurse to every 4 Dr Brookes appealed particularly for local help, though he would also be glad to have nurses from other parts of the country Recruitment, however, was unfortunately limited to the local district because of inadequate residential accommodation for nurses

The *Shrewsbury Chronicle* of Dec 9, in reporting this appeal, draws its readers' attention to the fact that the Ministry of Labour and National Service allows young men deferment from National Service if they are willing to start training as nurses before they are 18½ Under this arrangement, made in 1947, men who have completed their training are given an opportunity to work as nurses during their period of National Service

DISCUSSION GROUPS AND SMALL CONFERENCES

THE World Federation for Mental Health and the Josiah Macy, jun, Foundation, of New York, are the joint sponsors of a small international working conference on the Functioning of Discussion Groups and Small Conferences which is to be held in Eastbourne from Jan 31 to Feb 6 Varying methods of group discussion are increasingly employed at meetings, but, as they are not always as productive as they might be, it has been suggested that a useful manual might be produced as a result of the working conference Dr Brock Chisholm, who is a member of the executive board of the federation, is to be in the chair at the conference

HOSPITAL NEW YEAR

MANY administrators and doctors will face 1956 with more confidence because they have on an accessible shelf the current edition of the *Hospitals Year Book*[1] In it they will once more find in orderly array particulars of all hospitals and hospital authorities in Great Britain and Northern Ireland, the blood-transfusion services, Government departments, and statutory bodies The useful indexes to statutory instruments and official circulars have been brought up to date In his annual review Mr J F Milne, the editor, discusses the inadequacy of the proposed capital expenditure on hospitals, the problems of our mental hospitals, and the shortage of staff at all levels in all kinds of hospitals He believes that despite these difficulties the quality of the service offered to the patient has improved, "especially in endeavouring to see that he is treated as a person and not simply as a case"

Society of Apothecaries of London

At recent meetings of the court of assistants, with the master, Dr Neville Finzi, in the chair, Sir Horace Evans and Mr Alan Brews were elected to seats on the court, and it was resolved to confer on Sir James Paterson Ross the freedom of the society, honoris causa

The following were elected to the livery.

J B M. Coppock, A C Frazer, L J Wallace, A M Rackow

The following were elected to the freedom of the society by redemption

J D A Gray A J C Gormley, W D R Thompson, Elizabeth A King Turner

The following diplomas were granted

M M S.A—H A Evans, C J Goosen

L M S.S.A—A H Sears, M K C Lu, B M Hellings Evans J F Popper, R N *Gardiner, St J Dowling C* P K Watson, B H Gooch, R Dawkins, R C Rintoul, G B Middle, R D Sandfield, A H Atkinson, R M Burton

D I H—R H R *Aston*, J *G S Coetzer* J M *Davies*, A P Dikshit, H Miller, K N J Pocock, V G Springett

Liddle Prize

An award of this prize (£200) is to be made in 1958 The subject chosen for the essay is *the social and economic aspects* of epilepsy Further particulars may be had from the dean of the London Hospital Medical College, Turner Street, E 1

Nuffield Dental Fellowships

One of the aims of these fellowships is to enable graduates in medicine and science to qualify themselves to undertake teaching and research on dental health and disease Further particulars will be found in our advertisement columns

British Association of Plastic Surgeons

The following officers have been elected for 1956

President, Mr Wilfred Hynes, hon treasurer, Mr R P Osborne, hon secretary, Mr J P Reidy, other members of the council Prof T P Kilner Mr D N Matthews Mr Rainsford Mowlem, Mr R J V Battle, Mr P H Jayes, Mr J S Tough, Mr A B Wallace, and Mr H P Pickerill

Research into Ageing

Entries for the 1955–56 Ciba Foundation awards for research on basic problems of ageing should reach the foundation not later than Feb 10, 1956 Information about the awards may be had from Dr G E W Wolstenholme, the director of the foundation, 41, Portland *Place, London*, W 1

Royal Society of Medicine

The next award of *the Colyer prize will be made in* November It is offered for the best original work in dental science completed during *the previous seven years* by a dental surgeon who has qualified from a dental school in Great Britain or Northern Ireland not more than seven years ago Applications should be submitted to the prize committee of the society, 1, Wimpole Street, London, W 1, not later than June 30

Institute of Diseases of the Chest, London

Clinical demonstrations will be given by Dr N Lloyd Rusby and Mr T Holmes Sellors at the institute (in the grounds of Brompton Hospital, Fulham Road, S W 3) on Fridays from Jan 6 to March 23 Open lectures will be given on Wednesdays, from Jan 11 to March 14 All the meetings are open to doctors without fee and will be held at 5 P M

Reciprocal Agreement with New Zealand

A reciprocal agreement on *social security* between the United Kingdom and New Zealand was signed in Wellington on Dec 20 It will come into operation on April 1, 1956

Under the agreement the Ministry of Pensions and National Insurance will treat people who come to the United Kingdom from New Zealand as if they had paid contributions to the National Insurance scheme while they were in New Zealand, so as to enable them to qualify for retirement pensions, widows' benefits and sickness and unemployment benefits People who go from the United Kingdom to New Zealand will continue, as at present to receive any retirement pension or widow s *benefit for which* they may have qualified under the National Insurance scheme The New Zealand ministry of social security will, however treat them as if they had been resident in New *Zealand* while they were living in the United Kingdom so as to enable them to satisfy the conditions for New Zealand benefits, and will take into account the amount of any National Insurance benefit *to which* they are entitled The agreement also provides for the payment of sickness and unemployment benefits under the New Zealand schemes to people from this country

Anyone who thinks he may become entitled to benefit under the agreement should apply to his local Pensions and National Insurance office

General Board of Control for Scotland

Mr A A Templeton, C B E, J P, has been appointed a commissioner of the board in place of Sir Robert Bryce Walker, who has resigned

Dietetics Congress

The second International Congress of Dietetics will be held in Rome from Sept 10 to 14, 1956 Further particulars can be had from the Associazione Dietetica Italiana, via dei Penitenzieri n 13, Rome, Italy

Ministry of Health *Appointments*

Mr Robert Turton, the Minister of Health, has appointed Mr P Benner *to* be his *private* secretary and Mr E F Cooper to be his assistant private secretary He has appointed Mr W M F Vane to be his parliamentary private secretary

Anglo-French Exchange Bursaries

Short-term grants for work in France are offered again this year to British doctors and medical research workers by the *Institut National d'Hygiène in Paris* *Application forms* can be had from Dr G W Wolstenholme, director of the Ciba Foundation, 41, Portland Place, London, W 1 The closing date for applications is Feb 4

Modern Aspects of Rheumatic Disease

The British Postgraduate Medical Federation and Empire Rheumatism Council have arranged a consultants' conference on this subject from March 22 to 24 in London Sir Francis Fraser will *give the opening address* at 2 15 P M on Thursday, the 22nd Further particulars may be had from the general *secretary* of the Council, Tavistock House, (N) Tavistock Square, W C 1

Symposium on Venereal Diseases

The first International Symposium on Venereal Diseases *and the Treponematoses will be held in Washington, D C* from May 28 to June 1 It will be sponsored by the United States Public Health Service and the World Health Organisation Further particulars may be had from Dr C A Smith, division of special health services, Public Health Service, Department of Health, Education, and Welfare, Washington, 25, D C

National Association for Mental Health

The annual conference of this association will be held next year at Harrogate on April 12 and 13, under the chairmanship of Sir Charles Morris, vice chancellor of the University of Leeds The theme chosen is Mental Health and Personal Responsibility, and the speakers will include Prof G R *Hargreaves, Prof T Ferguson* Rodger, and Dr Mary Burbury Further particulars may be had from the secretary of the association, 39, Queen Anne Street, London, W 1

Fellowships in Clinical Research

The Medical Research Council invite *applications for* fellowships tenable at centres in the United Kingdom during 1956–57 from medical graduates who wish to prepare themselves for a career in clinical research

The awards will be made for one year in the first instance and will be renewable annually to a maximum of three years in all Stipend will be at the rate of £950–£75–£1100 per annum, with superannuation. Applications must be sponsored by the head of the appropriate department in the candidate's university or medical school and an undertaking will be required that a suitable academic post in a clinical department will be available to the candidate in that institution on satisfactory completion of the period of study under the fellowship Forms of application may be had from the secretary of the council, 38, Old Queen Street, London S W 1, to whom they must be returned not later than March 1 1956

Oxford Graduates Medical Club

A dinner will be held at the Royal College of Surgeons, Lincoln's Inn Fields, London, W C 2, on Friday, Jan 20, at 7 30 P.M., when Mr E A Crook will be in the chair Tickets (25*s*) may be had from Mr Selwyn Taylor, 3, Roedean Crescent, Roehampton, S W 15

CORRIGENDUM *Argentaffinoma*—In the articles and our annotation last week the name of Dr Albert Sjoerdsma was *incorrectly* spelt

Births, Marriages, and Deaths

BIRTHS

TALBOT—*On Dec 31* at Kings College Hospital to Rosalyn (nee Carrick) and John M Talbot—a son (Derek Michael)

LIFE
(BIOLOGICAL, NOT BIOGRAPHICAL)*

ROBERT PLATT
M.D Sheff, M Sc Manc, F R C P
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF MANCHESTER

WHEN Christopher Wren was making his experiments on blood transfusion and the intravenous injection of fluids, and 70 years or so later when that clergyman Stephen Hales was demonstrating and measuring the blood-pressure of the horse, an educated gentleman (and there were such) could comprehend the whole of science, and even contribute to it by his own observation and experiment

Yet I suppose even in the 17th century a reservation would have to be made for mathematics, which had already reached considerable maturity and complexity, especially in its application to astronomy and to navigation, so much older is it than the rest of science Napier, whose logarithms to base *e* still do not enter into the daily thought of most of us, died in 1617

Even in the 19th century, amateurs such as Mendel and Galton made observations which were the starting-point of a new science Today it becomes harder and harder to do so, although still not impossible, as we see for instance when technical advances bring the amateur into unexplored territory as with Hillary to Everest or Cousteau to the depths of the sea

Yet physics has split from chemistry, and even chemistry itself has split into so many fragments that the specialist in each branch has difficulty in understanding the language of his colleagues In medicine you need no reminder of how difficult it is becoming (as a colleague of mine has said) for one man to understand both cardiology and electrocardiography at the same time The difficulty is not simply that knowledge has increased in extent and complexity The point is that as we begin to explore any part of our own subject in greater depth we at once feel the need of knowledge and techniques which belong to sister sciences, and are not readily at our command For all these reasons it is a good thing from time to time to try to observe, if only as an interested spectator, some field of knowledge other than our own, and occasionally to be prepared to discuss it—even, as Schrödinger (1945) says in a similar context, "at the risk of making fools of ourselves" We cannot of course hope to become expert in other men's specialties, but we can see them from a point of view determined by our own interest, background, and training, and in doing so we may occasionally ask a new question even if it is unlikely that we supply an answer It is with these considerations in mind that I shall speak on some fragments of biological knowledge which I personally find interesting

Life at a Standstill

Our bold colleagues the surgeons, with the help of their equally enterprising anæsthetists, have been making tentative studies in hypothermia They have, I believe, reduced the human body-temperature, without disaster, to between 21° and 25°C, at which level the heart is slowed and so is cellular metabolism; and tissues can thus be deprived of their blood-supply for a longer period than would be normally compatible with survival

Biologists, who by recourse to animal experiment can usually be a move ahead, have succeeded in reducing the temperature of rats and hamsters to 0°C, and I have myself seen the experiments of Anjus and of Audrey Smith (Smith 1954) at the National Institute for Medical Research, at Mill Hill As the animal's temperature is progressively reduced, respiration and circulation are arrested The continuous record of the electrocardiogram slows down and then comes to a standstill Yet the blood does not coagulate Animals may be kept in an ice-bath in this state for an hour or so with a rectal temperature of −5°C In some cases crystals of ice appear in the tissues Yet when the animals are warmed they come to life again and behave like normal animals The reviving process needs some care and skill because it is important that the periphery is not warmed too rapidly, the process is carried on by diathermy As the temperature rises, artificial respiration is carried out for a short time until spontaneous breathing is re established The animals do not suffer from frostbite unless the tissues have been handled and the joints flexed while they were in a frozen state These experiments represent, I suppose, an extension of the natural phenomenon of hibernation, but they seem to me to pose certain questions on what constitutes life, at any rate in the mammal If our definition requires that the heart should be beating, and the blood circulating and the individual regularly exchanging carbon dioxide for oxygen, then clearly these animals are dead I am sure that they are legally dead, though physiologically they must be still alive

But really all that is new is that this vital standstill takes place in a mammal That life in the form of the seed of a plant can exist potentially for hundreds of years is of course well known Equally remarkable, though perhaps not so dramatic, is the fact that mammalian germ cells—for instance in rabbit ovaries—can be kept for a month or more at −79°C and by grafting into another animal can be made to function and produce new individuals And this brings us to one of my main topics which is the transmission of life from one generation to the next

Transmission of Life

I suppose the supremely important outcome of Mendel's work was that he showed *heredity to be* particulate where Darwin would have thought of it as blended For although Mendel's work was *published in* 1866, during Darwin's lifetime, it lay unheeded in an obscure journal (the Proceedings of the N[illegible] Verein in Brünn) until it was rediscovered in 1900 [illegible] after Darwin's death Darwin would have thou[illegible] each individual as a blend of its father and mot[illegible] two wines might be mixed in a bottle D[illegible] have expected (as you or I might) that if *you* [illegible] and dwarf peas you would get plants int[illegible] *between the two* Mendel showed that you did[illegible] obstinately remained either tall or dwarf and [illegible] proportions dependent upon the genetic [illegible] their parents If we want a simile for Mende[illegible] late inheritance we can think of [illegible] coloured beads in a bottle † Each bead [illegible] inherited *either* from father or from [illegible] l *individual inherits a* different assort[illegible] r either parent, and so the pattern of th[illegible] e *variable, and every individual* is [illegible] beads themselves, or the genes [illegible] de simile), are transmitted unchange[illegible] ei *millions of generations* [illegible] m

And one of the most fascinatin[illegible] hat *inheritance is that, like* mar[illegible] nce *equally well not only to mice* [illegible] hem *also to* plants and in fact t[illegible] can *sexually* Sex itself is of [illegible] to *inheritance*, and you will [illegible] of the X and Y chromo[illegible] *species* being the homo[illegible] [illegible] XY Since [illegible] germ-cells, which are haploid (that is containing only a single and not a double number of chromosomes and genes), all human ova are X whereas sperms are either X or Y. All the cells of the human body contain in their nuclei a replica of the 24 pairs of chromosomes, including of course the XY or XX pair which determine sex. It is therefore not surprising that recent work has established that certain sex differences can be discovered in somatic cells. An individual's sex may in fact be diagnosed from his leucocytes or more clearly by a skin biopsy.

---

* Presidential address to the section of medicine of the Manchester Medical Society, April 6, 1955 Also used at a meeting of the Royal Australasian College of Physicians, Dunedin, Sept 23, 1955

† [illegible] recollect who e[illegible]

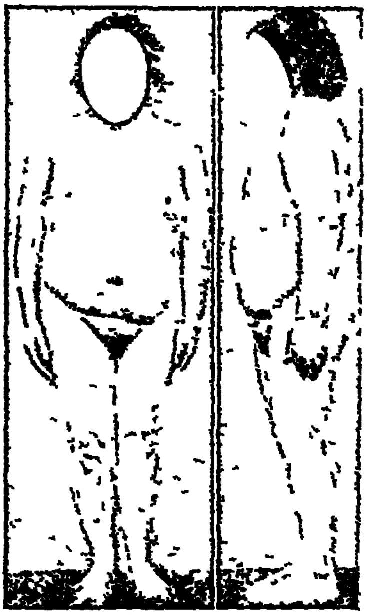

Fig. 1—A case of Turner's syndrome in which the genetic sex was male.

It has lately been found that in certain cases of ovarian agenesis, including those known as Turner's syndrome in which other congenital abnormalities coexist, the sex as determined by skin biopsy is male (fig. 1). These people appear to be female, but at the age of puberty they fail to develop secondary sexual characters. Examination shows an infantile vagina and uterus and no ovaries. Under the influence of œstrogens they can be transformed into apparently normal females except that, having no ovarian tissue, they are incapable of having children. One of our patients who was treated in this way (fig. 2) is successfully filling the female rôle of marriage to the satisfaction of both parties. It was only some years later when Polani, Hunter, and Lennox published their paper (Polani et al. 1954) that we discovered by skin biopsy that she is *genetically male*. Needless to say, this information has been kept to ourselves.

Biological Advantages of Sexuality

While on the subject of sex we may briefly consider the reasons in favour of sexual reproduction. Obviously sex is not necessary for the continuance of a race. Many primitive organisms divide and reproduce without sexual differentiation. Even in higher animals parthenogenesis may take place. The drone bee has no father. Loeb in 1899 was able to make starfish eggs develop without fertilisation. Bataillon in 1911 produced tadpoles from frog spawn by artificial stimulation. Gregory Pincus, in 1939, after a large number of experiments, produced three fatherless rabbits (Pincus 1939).

Why then has sexuality been adopted by all the higher species?

The union of two individuals has two major effects. One is that by Mendel's law of independent assortment, separate characters previously found in two different individuals may meet in the next generation and appear together in the same individual. Sexuality thus produces the new variants on which the process of evolution can act by natural selection. Darwin, who thought heredity to be a blending of characters instead of a reassortment, was aware of this difficulty to the acceptance of his theory of evolution, for a blended heredity would lead to uniformity. Tall and dwarf peas, for instance, would in the subsequent generations all end up as medium in height. He therefore postulated that sudden unpredictable variations, or mutations as we would now call them, were very important for evolution. We can now see that this is not so. Sex plus particulate inheritance—the gene system in fact—produces most of the necessary variation. Natural selection will favour the survival of new and advantageous products of sexual reproduction. Inbreeding within a small population will tend to limit the number of variants and new patterns, whereas outbreeding will increase them. This is no doubt one reason why we find in Nature many devices to discourage inbreeding, such as "*the heterostyly of the primrose and the Table of Kindred and Affinity of the Prayer book*" as Haldane (1954) observes.

Sexuality has, however, another major effect, somewhat in the opposite direction. It provides that all individuals are diploid—that is, they have a double set of genes and chromosomes. This makes for stability in the race, for new mutations, which are usually disadvantageous, are usually recessive and are not immediately apparent. It has, in fact, been calculated that a new mutation occurring today, either spontaneously or as a result of all the radiation at present being released in the world, would be unlikely to show itself for some 500 years. But this is no reason why we should neglect the problem, and of course a cousin marriage might bring two mutant recessive genes together much more quickly. One hesitates to think what might be the result of a cousin marriage in Hiroshima, or for that matter a marriage of cousins whose common grandmother had been a radiographer.

I have said that each individual is unique, a new pattern being formed although the genes themselves are transmitted unchanged. But both statements, of course, require qualification. Identical twins are the exception to the uniqueness of pattern, and mutations are the exception to the unchanging nature of genes.

It is now well known that there are two kinds of twins—those in which the fertilised ovum has split into

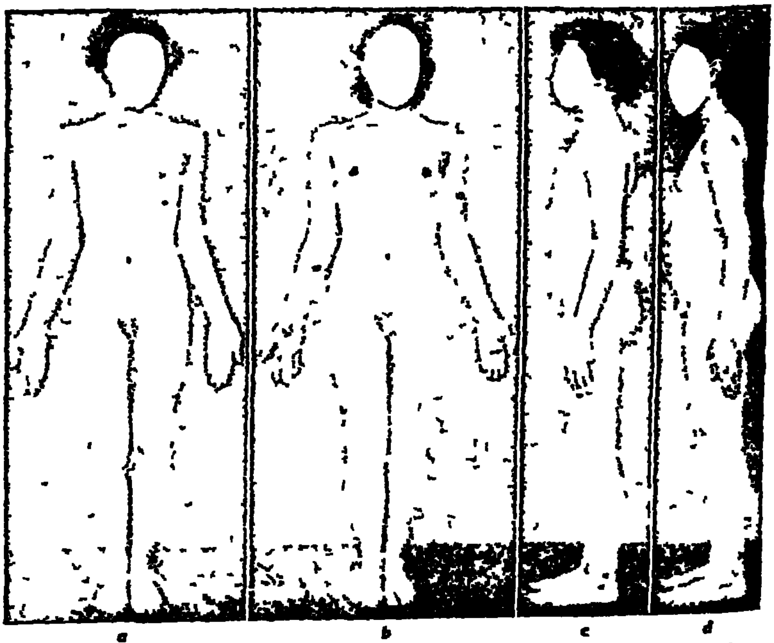

Fig. 2—A case of ovarian agenesis in which the genetic sex was male. *a* and *c* before treatment; *b* and *d* after treatment with œstrogens.

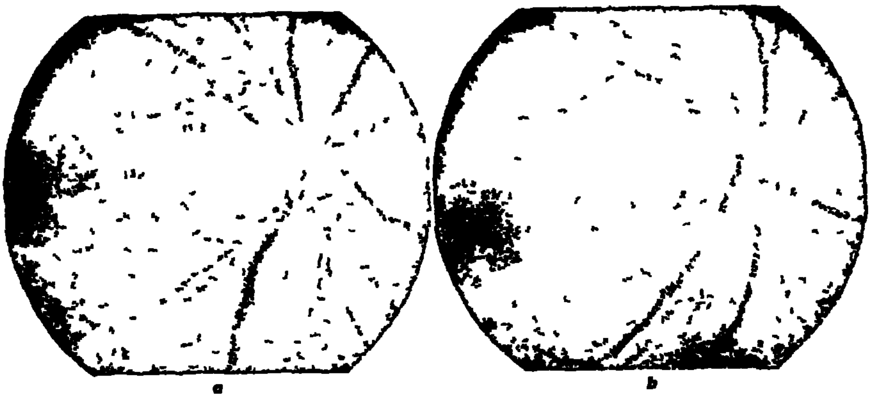

Fig 3—Retinal photographs from the identical twins illustrated in fig 4

two before going on to its normal embryological development (the so called uniovular or identical twins), and those in which two ova are fertilised by two sperms at the same time, and are simply brother and sister (or two brothers or two sisters) sharing the uterus at the same time. It is not so well known that there may be a third type of twin (obviously a theoretical possibility) in which the ovum splits into two before fertilisation and the two halves are fertilised by separate sperms. (Or alternatively the second polar body of meiosis is fertilised as well as the ovum.) In this case most characters transmitted from the mother would be identical in the two twins, whereas those derived paternally would be dissimilar in expected proportions. Not very uncommonly the resemblance between twins is far stronger than the resemblance which is usual between two siblings, and yet they differ in some obviously inherited characteristic such as hair or eye colour. No one, so far as I know, has made any important study of this problem. If a great enough number of twins, together with their two parents, could be assembled, and their blood groups examined, there might be statistical evidence of the existence of this type of twin. Taking the MN groups, for instance, the combination MN in one parent and N in the other should yield equal numbers of MN and N in the offspring. If twins are identical, all their blood-groups will of course be identical, but if there are significant numbers of dissimilar twins derived from one ovum and two sperms, there should be a greater likelihood of the twins inheriting the same group where the mother is the heterozygote than where the father is.

Coördination of Development

An interest both in retinal photography and in twins has led me with the help of Raymond Lawton to study the retinæ of identical and non-identical twins. The pattern of each retina is unique for each individual: it is as distinctive as his fingerprints or electrocardiogram. Hence, if identical twins had identical retinæ, retinoscopy would have been a ready and very useful method of distinguishing between uniovular and binovular twins. However, it turned out differently. Although with practice one can often pick out from a number of retinal photographs those which belong to a pair of identical twins, the vessels after they have left the disc are usually very unlike. One can in fact easily tell one twin from the other with an ophthalmoscope, even when it may be socially very difficult to do so (figs 3 and 4). It looks as if the genes lay down the general plan but not the full detail of our architecture, and that after a certain stage of development some kind of controlling or coordinating mechanism is in operation, as if "the organism knew in advance what it wanted" as Graham Cannon has said.

This kind of phenomenon has led some biologists, such as Cannon and the late Frederic Wood Jones, to wonder if Darwinian selection can account for all evolution and all the adaptations found in Nature. Take the development of the human eye for instance, says Cannon (and I hope I do not misrepresent him): it is inconceivable, he says, that it should develop without some process of coordination regulating the simultaneous development of retina, vessels, lens, and so on. Right, say the orthodox biologists, then no doubt there are inherited coordinating genes, which are so to speak in charge of the process. Then, says Cannon, those genes must have been evolved before the human eye could develop, so that the control of the process was laid down before the organ appeared. In other words Lamarck perhaps was somewhere near the truth when he postulated that it is the need of a new organ which results in its production.

Acquired Characteristics

There are, however, experimental as well as philosophical doubts as to the adequacy of orthodox views on evolution, and here the study of the genetic behaviour of primitive organisms such as moulds and bacteria has been very important. Why do tubercle bacilli become resistant to streptomycin, for instance? Do they learn to adapt their metabolism to it so that it is no longer harmful? If so, they clearly pass on this acquired characteristic to future generations. Or is this only Darwinism on a shorter time scale? Do a few bacilli exist from the beginning which by some natural mutation have all along been resistant to streptomycin? If so, they will survive when all their fellow bacteria are killed off and the new generations will come to be composed only of resistant strains developed by selection from these mutants.

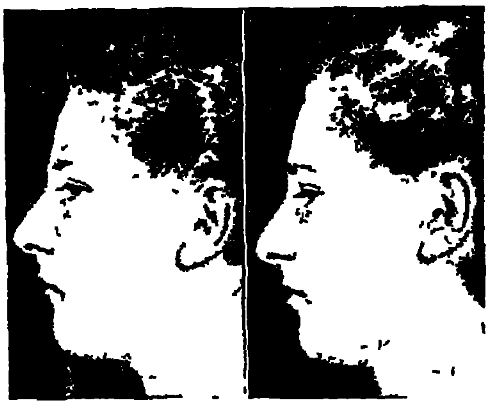

Fig 4—See fig 3

It is difficult to plan crucial experiments to decide between these alternatives. There is no doubt whatever that certain bacteria and moulds can be "trained" in the performance of certain biochemical processes: that is, they can be trained to do without a certain substance or to accept one which is normally poisonous to them. There is equally no doubt that this acquired ability can be passed on to future generations. The difficulty is to tell whether a new skill has been acquired, or an existing one developed, and in transmission to decide between true nuclear inheritance and protoplasmic transfer, and, in some cases, to exclude the possibility of virus transmission. Despite the difficulties, there seems to be evidence which satisfies such authorities as Haldane and

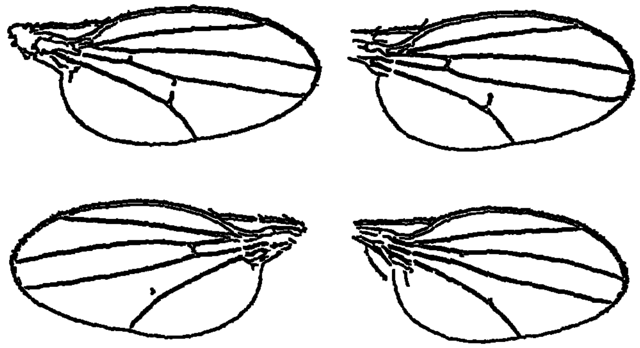

Fig 5—Defect in the posterior cross veins in the wings of *Drosophila melanogaster* (see text) (*Reproduced from* *Endeavour*)

Hinshelwood that in some cases the hereditary transmission of an acquired characteristic has been proved in the bacterial world

In higher forms of life, Waddington's recently reported transmission of an acquired characteristic in drosophila is important (Waddington 1952) If these flies are exposed to a temperature of 40°C for a few hours at a certain stage of their development, about 40% show a variant in the veins of the wing (fig 5) If now those which show the abnormality are bred among each other, in about twelve generations flies begin to appear (and eventually reach a prevalence of about 80%) in which the cross vein-less *abnormality occurs without the* application of the environmental stimulus The implication for evolution is this evolution by selection does not merely act on a series of chance variants but also affects the sensitivity of individuals to react to an environmental stimulus Thus if we may jump a long way from Waddington's experiment we see that, starting with a race of white *men who easily adapted to sunshine* by pigmentation, we might, by the action of selection in a tropical environment, end with a race of Negroes

Before leaving the subject of the transmission of acquired characteristics I must refer again to the possibility of virus transmission in some instances in plants and bacteria, and there is at least one instance of virus transmission *in the mammal Bittner studied* strains of mice susceptible to breast cancer In some strains a very large proportion of the adult female mice developed breast tumours He found, however, that if the mice of a non-susceptible strain are suckled by a mother of a susceptible strain and vice versa, transmission of the tumour tendency is by the milk line and not by the ordinary rules of heredity *It now seems certain that a* virus is transmitted in the milk, which gives rise to breast cancer in later life The possibility that this happens in the human species has not been ruled out

The study of genetics in simpler organisms such as bacteria and fungi has given rise to other discoveries By exposing fungi such as neurospora to X rays a large number *of mutant strains can be produced, each of which* seems to give rise to a specific and single block in the synthesis of certain amino acids Thus normal stocks of neurospora will grow on a minimal medium consisting of water, inorganic salts, glucose, and a trace of biotin The mutant strains fail to grow, but will do so if given the specific amino acid which they now fail to synthesise or in some cases a *precursor* In this way a good many metabolic pathways have been mapped out, some of which probably have an important *bearing on* cell metabolism in higher animals Indeed, mutations in the human subject, giving rise to "inborn errors of metabolism" are, as Archibald Garrod recognised years ago, blocks in the sequence of cell biochemistry

The Nuclear Material

The main substance of the nuclear genetic material appears to be desoxyribonucleic acid (D N A), and work by Watson and Crick (1953), which is rather exciting, though I do not profess to understand it, suggests a molecular structure for this compound which gives at the same time an inkling of how *nuclear material may* duplicate itself D N A, they postulate, consists of a *double chain arranged in helical* form (fig 6) The two chains are held together by hydrogen bonds between the organic bases which are part of the molecule, and in which, for physicochemical reasons, only certain linkages are possible Thus adenine must pair with thymine, and *guanine with cytosine If the two chains* come apart, as they presumably do before reproduction, each acts as a template on which another chain forms according to the design necessitated by the structure of the existing chain The original work should be consulted At the 1954 meeting of the British Association Dr Chayen cast doubts upon the likelihood of D N A being the essential substance of genes, but it is clearly associated with them It is not itself a protein, though it has a molecular weight of 1–4 million

Some very interesting observations have lately been made on the genetic functions of this substance D N A, *which seems to be just as important in the genetics of* bacteria as it is in man Hotchkiss (1953–54) and others have shown that unencapsulated relatively avirulent pneumococci can be made into virulent encapsulated organisms by transferring D N A from killed organisms of the encapsulated type Now the capsules consist largely of polysaccharides, so it is definitely not the capsular substance which is being transferred, but the genetic control of its development

Perhaps even more remarkable, the same workers have shown that drug resistance in pneumococci—for instance, resistance to penicillin or streptomycin—can be transferred to non-resistant strains by transfer of an extract which contains D N A but as far as possible is freed from all other components of the resistant organisms The resistance so transferred is then transmitted through succeeding generations

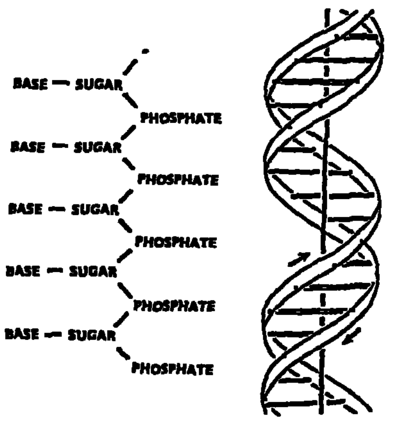

Fig 6—Structural formula of desoxyribonucleic acid (see text)
(*Reproduced from* *Nature*)

Obviously I am even less well equipped to discuss *these matters of* bio physical-chemistry *than I* am most of the rest of the material of this lecture, but having got so far I would like at least to allude to some of the work of Krebs on cellular metabolism (Krebs 1953), for one cannot consider life simply as a beginning and end without even asking how it is maintained in the individual The beauty of Krebs's concepts is that, like others we have *been discussing, they appear to be as applicable* to protozoa as to the higher mammals, and probably with reservations to plants and *bacteria as well* He shows how the initial phase in energy production is the breakdown of large molecules of foodstuffs into smaller units The next phase is the partial oxidation of these into only three substances—acetyl co enzyme A α ketoglutaric acid, and oxalo acetic acid The utilisation of these provides the energy which is built up into that universal storage *battery of* chemical energy A T P (adenosine triphosphate) which seems *to* be the source of all readily available energy for body processes *It seems certain* that A T P (or in some cases I T P —inosine triphosphate) supplies energy for the osmotic work of cells, for the contractile phase of muscular work (Weber 1953–54), and probably for the resynthesis of acetylcholine hydrolysed during nervous conduction (Nachmansohn 1953–54)

Disease and Natural Selection

Having thus skated on some extraordinarily thin ice I shall pass on to matters which I can understand rather better—back to human disease and the end of life Now that so many of the hazards of infancy, and the infective disorders of the young, have been mastered by the progress of scientific knowledge, more of us die of what we think of as the great constitutional diseases—atheroma (with coronary occlusion and myocardial infarction), hypertension, and cancer When we use that old-fashioned term constitutional, we infer that there is something inherent in the make up of the individual which, no doubt along with environmental influences such as cigarette smoking and being a doctor, renders the person liable to a disease which does not seem to be determined by such obvious external factors as trauma or infection Though we know little enough of these diseases, two things at least are clear about their ætiology One is that hereditary factors are important (They may not be very apparent in most cases of cancer, but critical investigations have usually revealed them in some form In hypertension they are much more in evidence, and I have myself contributed to the investigation of this phenomenon) The second is that they all tend to occur not so much in old age as in what we euphemistically call middle life, 45–60 years old We all know exceptions, but no one of us would deny that cancer and severe hypertension are commoner at 55 than they are at 35

As both Medawar (1951) and Haldane (1954) have pointed out, if a disease is partly determined by heredity and if the age of its onset is also under hereditary influences, then natural selection will gradually determine that it occurs more and more in the post-reproductive period, which we may call 45–60 when most of us have finished having families For a man or woman who had one of these disorders in a form in which it occurred at the age of 30 would on the average have fewer children to whom to pass on the hereditary influence

So it seems that the reason why these diseases attack us in so-called middle life is that evolutionary processes have pushed their incidence back towards that age After the reproductive period, so far from being selected out of the population, selection will if anything tend to favour these diseases (as Haldane somewhat cynically remarks), since the survival of a race will be favoured by not having too many elderly folk for the young ones to support And so you may infer that the prevalence of coronary thrombosis among physicians is really Nature's answer to the problem of the Senior Registrars

Clonal Ageing

My last topic is clonal ageing, and I am glad to see that there has been a revival of interest in this subject

A clone is a group or family of individuals all derived from a single cell In primitive organisms such as paramecium, and in plants, where reproduction may be sexual or asexual, a single fertilised cell, the result of sexual conjugation, may divide and divide again by a series of mitoses until a large number of individuals have resulted They then undergo, all at the same time, some ageing process, and unless a further sexual conjugation has taken place, the line will give out and the cells will reproduce no longer Sonneborn (1955) has explored the reasons for this in paramecium, and finds it to be due to inaccurate copying processes in mitotic division

You may ask what bearing this has on higher organisms But if you think of yourselves you will realise that every cell in the human body is the result of the asexual mitotic division of another cell, and that, in turn, of another cell, and so on until we get back to the single fertilised ovum from which we all originated It often gives me some quiet satisfaction to realise that whatever you may think of yourselves biographically, biologically you are nothing but a lot of clones If geriatrics ever becomes a science it may owe more to professors who study paramecium than to those who work at the bedside, important though the latter's work may be in a social and humane context

Life and Death

In conclusion I return to Schrodinger's introduction to his little book "*What is Life?*" In it he quotes Spinoza as saying "There is nothing upon which a free man ponders less than death, his wisdom is to meditate not on death but on life" If by this Spinoza meant what I think he meant, then I disagree, for I believe that a wise man, at any rate when he reaches the post reproductive age, should meditate now and then upon death, if only to face it courageously should it announce its coming in advance Though perhaps not with the morbid preoccupation of Charles Morgan's *Sparkenbroke*, I nevertheless find death a fascinating subject, and perhaps at some future time I may be permitted to address you on that theme If so I shall of course be under the handicap of not being able to speak from personal experience

I am grateful to Professor Waddington and the Editor of *Endeavour*, and to Dr Watson and Dr Crick, and the Editors of *Nature*, for permission to use figs 5 and 6

SEROLOGICAL EPIDEMIOLOGY OF POLIOMYELITIS

DISTRIBUTION OF IMMUNITY TO POLIOMYELITIS VIRUS

R J Fallon
B Sc, M D Lpool
ASSISTANT LECTURER IN BACTERIOLOGY IN THE UNIVERSITY OF LIVERPOOL

Over the last eighty years the incidence of poliomyelitis has much increased, especially in Scandinavia (where the first large epidemics were observed), North America, Australasia, and Western Europe Epidemics have occurred elsewhere, particularly in some island communities, but in the main have not been so large as in the above-mentioned areas

In those countries where epidemics occur frequently there has been a shift in the age group attacked Whereas poliomyelitis most often affected children younger than school age in the earlier part of the present century, it now most often affects children of school age, adolescents, and young adults This change has not been noted in those countries where epidemics either have not occurred or have only occurred in the last few years

The countries principally affected by epidemic poliomyelitis are those where the standard of living is high, and Olin (1951) suggests that in these countries the chances of coming into contact with the virus at an early age have been reduced, compared with the chances in the underdeveloped countries of the world. This being so, contact with the virus takes place at a later age in highly civilised countries; and, as with many other viruses, when infection does take place, the manifestations are more severe than they would have been if infection had taken place earlier in life.

Serological surveys have shown that contact with the virus of poliomyelitis does take place at an early age in the underdeveloped areas of the world (Paul et al. 1952, Paul 1954), and that in America (e.g., Melnick and Ledinko 1953) early infection with the three types of poliomyelitis virus does not take place to the same extent as in Cairo and North Africa.

In this country poliomyelitis has occurred in wide spread epidemic form only since 1947. The reasons why epidemics appeared later in this country than in other countries with a high standard of living are not clear. Serological surveys may shed some light on this problem.

Present Investigation

Bradley (1954) notes that eighteen areas in England and Wales did not notify cases of poliomyelitis in 1922–52 inclusive. The largest area had a population of 9400; the others had much smaller populations. Bradley suggests that these areas escaped because they had not been exposed to the virus. It was decided to investigate Betws-y-Coed in North Wales because no notification of poliomyelitis had been received from there since poliomyelitis became notifiable in 1912. Liverpool, where poliomyelitis occurs annually, was used for comparison.

Sera obtained from children in both Betws-y-Coed and Liverpool were examined for antibodies to the three types of poliomyelitis virus. The child population was surveyed because they are less likely than adults to have acquired antibodies to poliomyelitis virus outside the areas in which they live. Furthermore, the level of serum antibodies to poliomyelitis virus in the child population reflects the recent prevalence of the virus in the community.

During these surveys attempts were made to isolate poliomyelitis virus from the sewage of Betws-y-Coed. The methods of ammonium sulphate precipitation (Gard 1940) and ultracentrifugation (Melnick 1943) and a combination of the two (Melnick 1947) were used without success.

AREAS SURVEYED

Betws-y-Coed is a village in North Wales with a population of about 750 (Registrar-General's estimate for mid-1954), this figure having varied only slightly in recent years. The village is a popular holiday resort, many people visiting it for the day in addition to those staying for longer periods. All children of school age up to 11 years attend the local county primary school. Some children then proceed to a grammar school in a neighbouring town, the remainder continuing to attend the local school until they reach the age of 15. Apart from the holiday trade the principal local occupation is agriculture, and some of the children attending the primary school live either on farms or in houses outside the village. The village's water supply comes from a reservoir in the neighbouring hills and is chlorinated. The school and all the houses in the village have satisfactory drainage, the untreated sewage effluent being discharged into a river about ¹/₂ mile below the village.

Liverpool is an industrial port with a population of about 786,000 (Registrar General's estimate for 1954). Some of the population live in tenements, and there are still some overcrowded slums in the city. Apart from this the general housing is moderately satisfactory. Poliomyelitis has occurred with increased frequency during the last few years, the largest outbreak being in 1951, when 135 cases were notified.

POPULATION EXAMINED

In Betws-y-Coed samples of blood were obtained during the winter of 1954–55 from children attending the local infant-welfare clinic and the county primary school. Their ages ranged from 7 months to 14 years. Of an estimated child population of 176 aged 0–14 years, serum was available from 78.

In Liverpool, children's sera were obtained from hospital laboratories to which they had been sent for other investigations. No child with a history of poliomyelitis was included in the survey. The age range was the same as that for Betws-y-Coed. 71 sera were examined from Liverpool.

METHODS

Sera were obtained by venepuncture or by heel puncture according to the child's age. After inactivation at 56°C for 30 minutes sera were examined initially at a dilution (after addition of virus suspension) of 1:10. Those sera from Betws-y-Coed which neutralised one or more types of poliomyelitis virus were re-examined at a final dilution of 1:100, whereas those which did not neutralise at 1:10 dilution were re-examined at a final dilution of 1:2 against the appropriate virus types.

Tissue cultures used for examining sera were either of rhesus monkey kidney or of HeLa cells. Most of the sera were examined by using cultures of monkey kidney, and all the serum titrations were done in these cultures. Two types of monkey-kidney cultures were used: fragment cultures and cultures of trypsin-dispersed kidney. The latter were set up by the method first described by Dulbecco and Vogt (1954) and modified by Youngner (1954). Before fragment cultures were used for neutralisation tests or for virus propagation, the fragments were shaken off the roller tube wall, leaving the sheet of epithelial outgrowth behind. The culture medium used for most of the tests was that described by Melnick et al. (1954), except that Earle's balanced salt solution was used instead of Hanks' solution. HeLa cells were maintained as described by Syverton et al. (1954), except that trypsin dispersion of cells before subculture was abandoned in favour of dispersion of cells by simply pipetting the cell suspension (obtained by scraping the cells off the tube wall) up and down until most of the cell clumps were broken up. A modification of the medium described by Kret (1955) proved satisfactory for maintaining the cells when they were being used for either neutralisation tests or virus propagation.

Virus strains were: type 1, Mahoney strain; type 2, Y SK strain; type 3, Saukett strain. They were received from the Central Public Health Laboratory, Colindale. Virus pools were made by passage of the three strains in cultures of monkey kidney or HeLa cells, and the same pools were used throughout these tests. The titres of the aliquots of each pool were determined before their use in the neutralisation test. The 50% infectious dose for tissue culture (TCD50) was calculated by the method of Kaerber (1931).

Tissue culture neutralisation test.—Serum neutralisation tests were set up by the method described by Ledinko et al. (1952). Equal volumes of diluted inactivated serum and a suspension containing 200 TCD50 of the appropriate type of virus in each 0.1 ml. were mixed and allowed to stand at room temperature for 1 hour. Mixtures of each serum with each of the three types of poliomyelitis virus were set up. After 1 hour 0.1 ml. of each virus-serum mixture was pipetted into each of two tissue-culture tubes from which the culture medium had been removed. 0.1 ml. of a mixture of serum and balanced salt solution was pipetted into one culture tube, which acted as a serum control. With each test six cultures were used for virus controls, two tubes being inoculated for each type of virus, the final dose of virus being the same as in the neutralisation tests—i.e., 100 TCD50. Cultures were left at room temperature on the bench for 30 minutes to ensure maximal contact of the inoculum with the cells. At the end of this time cultures received 1 ml. of medium and were then placed in a roller drum at 37°C and after 5 days examined by low-power microscopy. The presence of antibody was indicated by the absence of "cytopathic" changes in the cultures, which changes were evident in the virus control tubes. Positive sera of known antibody content were not available when the testing was begun.

RESULTS

Betws y-Coed

The distribution of antibody to any type of poliomyelitis virus in relation to age is shown in fig 1 Only 8 of the children were without antibody to one or more types of virus, and 5 of these were aged less than 2 years Infection with type-1 virus has been commoner than with any other type (fig 2) Antibodies to this virus type were present in some sera from even the youngest children, indicating that infection with type-1 virus had taken place in the village within the year preceding this investigation

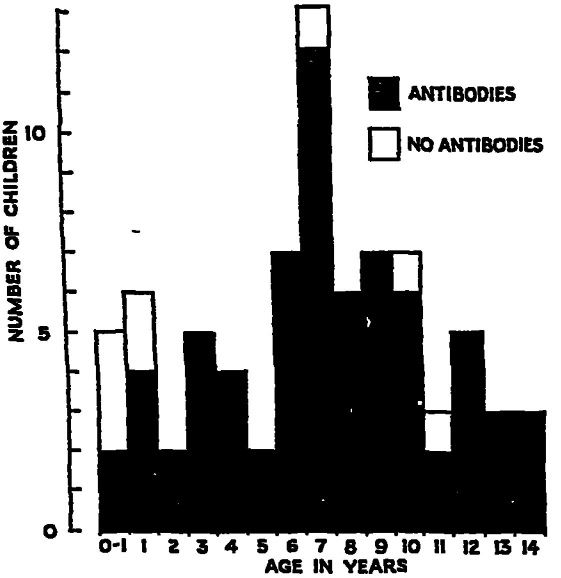

Fig 1—Numbers of Betws-y Coed children with and without antibodies to poliomyelitis virus in a final serum dilution of 1 10

The distribution of antibodies to type-2 virus is shown in fig 3 Except one child, aged 8 months, who had antibodies to all three types of poliomyelitis virus at a titre of 1 10, no child aged less than 2 years had antibodies to type 2 virus It appears that infection with type-2 virus either had not taken place or had been very limited in distribution during the two years preceding this investigation

Antibodies to type 3 virus were the least common in sera from Betws y-Coed (fig 4) Except in the child already mentioned they were not present in the sera of children aged less than 3 years Table I shows the numbers of children with antibodies to one, two, or all three types of poliomyelitis virus in each 5 year age-group The figures show that the age group 5–9 years had the highest proportion of children with antibodies to two or three types of poliomyelitis virus (83%) Even in the age group 0–4 years 8 (36%) of the 22 children examined had multiple antibodies, illustrating again the widespread infection with poliomyelitis virus in this community

TABLE I—NUMBERS OF CHILDREN EXAMINED FROM BETWS-Y-COED WITH SERUM ANTIBODIES TO ONE OR MORE TYPES OF POLIOMYELITIS VIRUS (1 10 SERUM DILUTION)

—	Age-group (yr)			Total
	0–4	5–9	10–14	
No of children examined	22	35	21	78
No of children with antibody to a single type of virus	9	5	6	20
No of children with antibodies to two types of virus	4	15	5	24
No of children with antibodies to all three types of virus	4	14	8	26
No of children with no antibody	5	1	2	8

After the sera had been tested for antibodies, inquiries were made into family relationships It was found that 44 of the sera had been obtained from 2 or more children from each of 17 families None of the children coming from these family groups had escaped infection with at least one type of poliomyelitis virus, and within each family the children had antibodies to at least one virus type in common In 9 family groups the children within each family had been infected with the same virus types In 4 families the youngest child lacked antibody to one type which the elder children had, and in one other family the youngest child had antibody to one more virus type than had the elder children Although antibodies to all three types of virus were found among children living in isolated dwellings, antibody to type-1 virus was less common among them than among the village children (Of the 15 children living outside the

Virus type	No of sera having highest titres of		
	1 2	1 10	1 100 and over
1	1	40	14
2	1	23	27
3		19	18

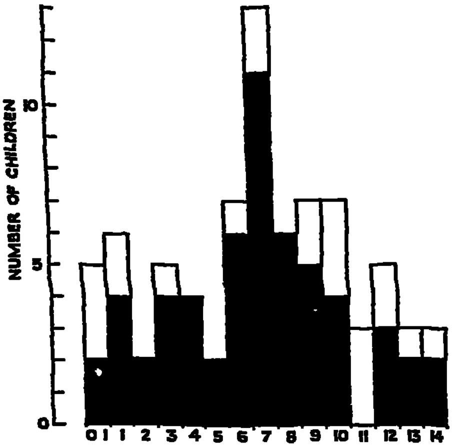

Fig 2—Numbers of Betws-y Coed children with and without antibodies to type-1 poliomyelitis virus in a final serum dilution of 1 10

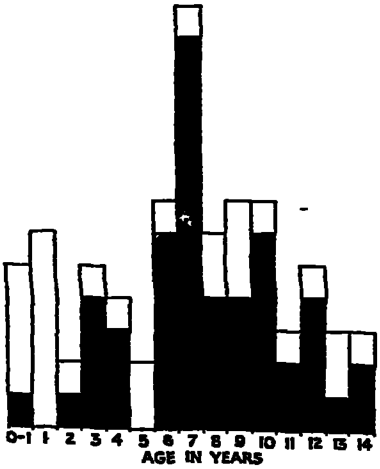

Fig 3—Numbers of Betws-y-Coed children with and without antibodies to type-2 poliomyelitis virus in a final serum dilution of 1 10

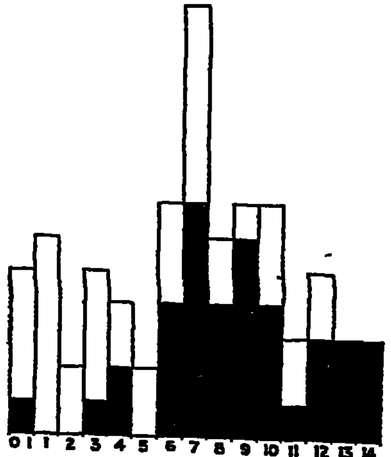

Fig 4—Numbers of Betws-y-Coed children with and without antibodies to type-3 poliomyelitis virus in a final serum dilution of 1 10

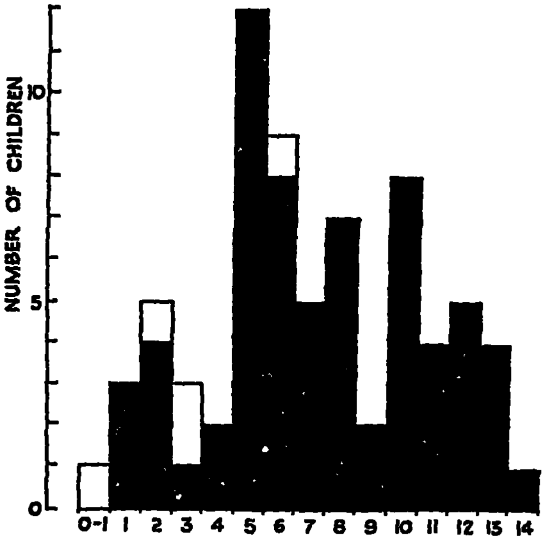

Fig 5—Numbers of Liverpool children with and without antibodies to poliomyelitis virus in a final serum dilution of 1 10

village 14 were aged 6–13 years, and, if the numbers of these children with *type 1* antibodies are compared with the numbers of children living in the village and having *antibodies to type-1 virus, it appears that*, whereas 5 of 14 children living outside the village had antibody to type 1 virus, 32 of 37 *children in that age group* living in the village had antibody to that virus type)

Table II shows the titres of serum antibodies *to the* three types of poliomyelitis virus found in Betws-y-Coed Titres of 1 100 or over were less common for antibodies to type-1 virus than for antibodies to the other two types This might well depend on the strain of type 1 virus used in the tests

Liverpool

The numbers of children examined in each age group with or without antibodies to one or other of the three types of poliomyelitis virus are shown in fig 5 As was noted for Betws y-Coed, the children with no antibodies to poliomyelitis virus were mainly in the younger age-groups Of the 71 Liverpool children examined 66 (93%) had antibodies to one or other of the types of poliomyelitis virus This shows that, in this area also, infection with *the virus of poliomyelitis* has been extremely common in recent years Figs 6–8 show the numbers of Liverpool children *in each age group* with antibodies to the three types of virus It can be seen that infection with each type of virus has taken place in almost every age group, there being no suggestion that any one type had been absent from the community in recent years Infection with types 1 and 2 has been more common than infection with type 3 virus Thus, whereas 45 children were infected with type-1 virus and 46 with type 2, only 29 children had antibodies to type 3 virus

Table III shows the numbers of Liverpool children in each five-year age group with antibodies to one, two, or all *three types of poliomyelitis* virus In the youngest age group (0–4 years) none of the children examined *had been infected with all* three types of virus, but 5 had been infected with two types Infection with more than one type of virus appears to have taken place in similar proportions of children in the 0–4 and 10–14 age groups in both areas surveyed, but in the age group 5–9 years it had apparently been less common in Liverpool than in Betws y-Coed

Discussion

The extent of infection with the three types of polio myelitis virus in *both of the* areas surveyed, revealed by tests for neutralising antibody, is compared in figs 9–11 with that in *children in two other communities*—Cairo in Egypt (Paul et al 1952) and Winston Salem in the U S A (Melnick and Ledinko 1953) In Cairo clinical infection appears to be uncommon, whereas Winston Salem had an epidemic of poliomyelitis shortly after the collection of the sera from which the results illustrated were obtained

Fig 9 shows that in Betws-y-Coed antibody to type 1 virus was more commonly found than in Cairo and in Liverpool For type 2 virus the rate and extent of infection in Betws y-Coed and Cairo appear to be similar, except that the 1-year old group in Betws y-Coed had not yet experienced infection with this type of virus

TABLE III—NUMBERS OF CHILDREN EXAMINED FROM LIVERPOOL WITH SERUM ANTIBODIES TO ONE OR MORE TYPES OF POLIOMYELITIS VIRUS (1 10 SERUM DILUTION)

—	Age group (yr)			Total
	0–4	5–9	10–14	
No of children examined	14	35	22	71
No of children with antibodies to a single type of virus	5	12	9	26
No of children with antibodies to two types of virus	5	15	6	26
No of children with antibodies to all three types of virus		7	7	14
No of children with no antibody to poliomyelitis virus	4	1	0	5

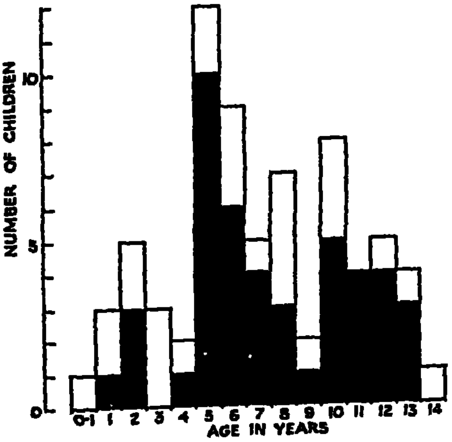

Fig 6—Numbers of Liverpool children with and without antibodies to type-1 poliomyelitis virus in a final serum dilution of 1 10

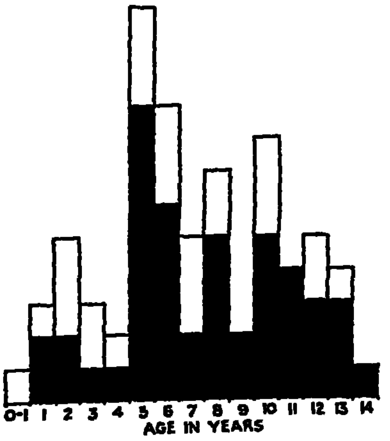

Fig 7—Numbers of Liverpool children with and without antibodies to type-2 poliomyelitis virus in a final serum dilution of 1 10

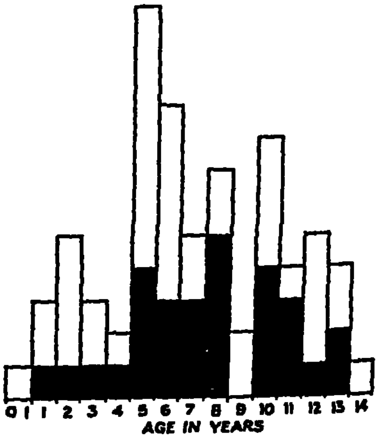

Fig 8—Numbers of Liverpool children with and without antibodies to type 3 poliomyelitis virus in a final serum dilution of 1 10

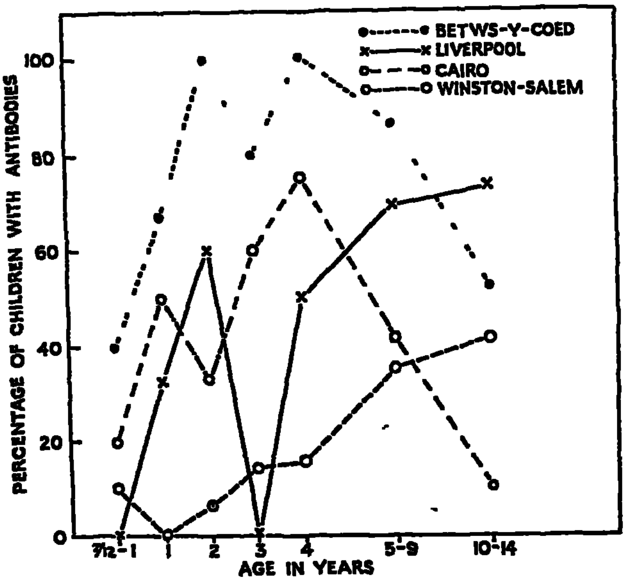

Fig 9—Prevalence of antibodies to type-1 poliomyelitis virus in different populations

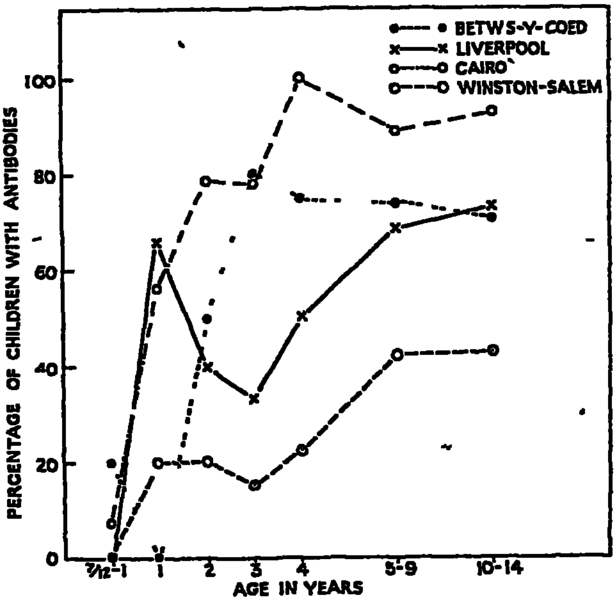

Fig 10—Prevalence of antibodies to type-2 poliomyelitis virus in different populations

(fig 10) Liverpool children showed less evidence of infection with type-2 virus Infection with type-3 virus has apparently been less common in the two areas surveyed than in Cairo (fig 11) Infection with all three types of virus appears to have been less extensive in Winston Salem than in Betws y-Coed and Liverpool, although the difference for type 3 is not so obvious

The results of the examination of children within families in Betws-y-Coed agree well with the findings of others who have shown that poliomyelitis virus is rapidly spread to susceptibles within the family (Zintek 1947, Brown et al 1948, Bhatt et al 1955, and others)

The reasons for the absence of notifications of clinical poliomyelitis from Betws-y-Coed are not clear It is quite conceivable that clinical non-paralytic infection has taken place without being recognised, indeed, it is very dubious whether abortive infection is ever recognised in the absence of an epidemic The absence of a frank paralytic case is not easy to explain but may be related to the small size of the community and possibly to the high rate of infection at an early age

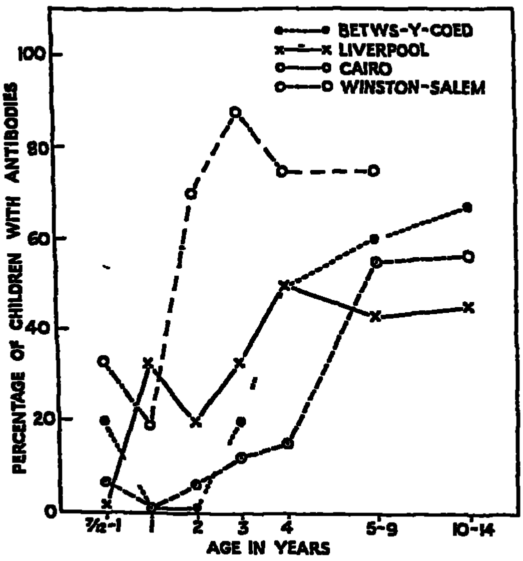

Fig 11—Prevalence of antibodies to type-3 poliomyelitis virus in different populations.

This survey therefore shows that, in both areas, infection with all three types of poliomyelitis virus, and especially with types 1 and 2, must have been widespread How far these findings are applicable to the country as a whole cannot be estimated, but the finding that infection has been more widespread at an early age in this country than in America may partly explain the lower incidence of clinical poliomyelitis in Britain

Summary

The sera of children from Betws-y-Coed and Liverpool were examined by tissue culture methods for antibodies to the three types of poliomyelitis virus

Infection with all three types of poliomyelitis virus has apparently taken place recently in both areas, infection with types 1 and 2 predominating

Although clinical infection with poliomyelitis virus has been observed in Liverpool, no case has been reported from Betws-y-Coed

The findings are discussed in relation to the incidence of poliomyelitis in the two areas and to similar serological surveys in other countries

I wish to thank Dr D E Parry-Pritchard, county medical officer of health for Caernarvonshire, and Dr T Heber Pierce, divisional medical officer of health for North Caernarvonshire, for their coöperation, Mr J Glynn Hughes, Mr C A Kortegas, M S I.A, and Miss E Williams, health visitor, for their help at Betws y-Coed, and Dr E G Hall, Dr J S Elwood, and Dr C A St Hill, and Sister S Hetherington for supplying sera from Liverpool children

THE treatment of gastric and duodenal ulcer has generally been based on the assumption that gastric juice, by virtue of its peptic activity, is one of the factors which prevent healing of the ulcer—if, indeed, it has not been assumed to be the principal factor in causing the initial breach in the mucosa The Sippy régime aimed at eliminating peptic activity by neutralising the hydrochloric acid in the gastric juice, and it may possibly have had this effect throughout most of the day if administered according to Sippy's instructions

Sippy (1915) gave hourly feeds of milk, eggs, and purées from 7 A M to 8 P M and sufficient alkali midway between each feed to prevent free hydrochloric acid appearing in the juice immediately before the next The last feed was followed by half-hourly doses of alkali for 2–2½ hours and the gastric contents were aspirated two or three times in the night so long as "excessive night secretion" persisted (i e, an amount of more than "about 10 c c")

The régime was onerous for the patient and required constant nursing attention, for practical reasons it has seldom been followed according to Sippy's exact instructions Any less strict technique is certainly inadequate to produce continuous neutralisation Nicol (1939), for example, found that hourly feeds of milk and vegetable purée, with 1 drachm of alkali four times a day, not only failed to neutralise the gastric contents but had less effect than an ordinary light diet, given at 2–3 hourly intervals

Nicol gave a powder consisting of 1 part of heavy magnesium carbonate, 1 part of calcium carbonate, and 2 parts of sodium bicarbonate In addition he gave ½ oz of olive oil and atropine sulphate gr 1/200 thrice daily

A more promising technique was introduced by Winkelstein (1932, 1933), who tried to achieve neutralisation over the whole 24 hours by giving patients a continuous intragastric drip of milk, to each quart of which was added 5 g of sodium bicarbonate With this method ulcers which would not respond to standard forms of treatment have healed rapidly (Winkelstein et al 1942) Other investigators have also reported good results with the treatment (Clark 1950, Garlick 1949), and have particularly stressed the rapidity with which otherwise intractable pain is relieved Reports of controlled trials of the method are, however, lacking

Method

We have tried to assess the therapeutic effects of continuous intragastric milk drip by means of a controlled trial The investigation was conducted in three parts, which were similar in general outline but differed in detail in the administration of the drip and in the use of ancillary treatments In each part of the investigation patients with fresh gastric ulcers were admitted to hospital, and then, if considered clinically suitable for inclusion in the trial, they were divided at random into two groups Patients in one group were kept in bed and given a standard medical régime, while patients in the other group were treated in the same way but were also given a course of milk drip

Parts A and B of the investigation were carried out in the course of a long-term research into the treatment of gastric ulcer In these parts the two main treatment groups were further divided into subgroups of four patients, and each member of a subgroup was allocated at random, in a similar way, one of four combinations of two ancillary treatments, thus (1) treatment X and treatment Y, (2) treatment X alone, (3) treatment Y alone, or (4) neither additional treatment With this experimental design it is possible to assess the effect of three forms of treatment on the same group of patients The results obtained with milk drip can be compared directly with the results obtained without milk drip, since both groups are comparable in respect of the proportion of patients receiving ancillary treatment Similarly the results obtained with each of the ancillary treatments can be compared with the results obtained in the corresponding control groups of patients who did not receive them Possibly the different treatments might have a synergistic effect on one another, so that although no effect was produced by one alone an effect might be produced by two or more in combination The existence of such an effect can, however, be recognised from inspection of the results, and if present can be allowed for in the analysis Details of the type of patient admitted to the trial, of the method of allocation to the treatment groups, and of the basic method of treatment, apart from the special methods under investigation, are described in a previous paper (Doll and Pygott 1954)

In *part A* of the investigation the main ancillary methods of treatment were the administration of 'Robaden' and of cabbage juice Another treatment used in a small group of patients was the routine administration of atropine (dry extract of belladonna gr ½ in pill form three times a day)

In *part B* of the investigation the additional forms of treatment consisted in the substitution of a normal hospital diet, less fried food, for the standard "basic" and "convalescent" gastric diets (Doll et al 1956), and advice to smokers to stop smoking The results obtained with robaden and with cabbage juice and the results obtained by varying the standard diet have been reported separately (Doll and Pygott 1954, Doll et al 1956) These treatments appeared to have no effect on the rate of healing of the ulcers Insufficient patients have been treated with atropine, or by advice to stop smoking, to enable any conclusion to be reached about their value No suggestion of any "interaction" has been observed between them and treatment with milk drip, and, in view of the way in which the investigation was designed, it is believed that any effect attributable to them can be ignored in making the comparison between the patients who were given milk drip and those who were not

In *part C* of the investigation no other ancillary treatment was under investigation, and all patients in both drip and control groups were given a modified Meulengracht diet, patients in the control group were given, in addition, 4 g of an alkaline powder every 2 hours during the day

The alkaline powder comprised sodium bicarbonate 3 parts, calcium carbonate 3 parts, light magnesium carbonate 3 parts, bismuth carbonate 1 part

The results of treatment were assessed subjectively by recording the patient's description of his symptoms, and objectively by measuring the change in the size of the ulcer niche A barium meal examination was made immediately after the patient's admission to hospital and

---

* We regret to have to record that Dr Price died on Nov 28—Ed L

2–4 days before the specific treatments were instituted A second barium-meal examination was made after the completion of the courses of treatment, exactly 4 weeks after the first examination The method by which the size of the ulcer niche was estimated, and the precautions taken to ensure, so far as possible, that the results of the radiographic examinations before and after treatment were comparable, have been described previously (Doll and Pygott 1954)

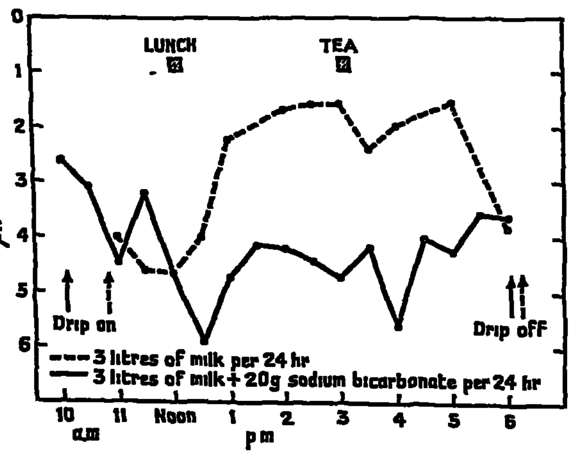
Administration of Milk Drip

The ordinary apparatus used for other forms of drip infusion was connected to a piece of thin rubber tubing, which was passed into the stomach through the nose or, if preferred by the patients, through the mouth Surgical drainage tubing $^1/_{20} \times {}^1/_{40}$ in was used instead of a Ryle's tube because it was thinner, more pliable, and more readily tolerated by the patient The tube was kept in the stomach for the whole period of 24 hourly administration of the drip, save that patients were allowed to remove it for half an hour after breakfast when they got up to wash Most patients, however, preferred to disconnect the tube from the drip apparatus and to keep it in situ The same meals were served to patients on the drip as to the control patients not on the drip, and all were encouraged to eat as much of the meals as they could

In *part A* of the investigation patients on drip were given by this method 6 pints of milk every 24 hours for 2 weeks, the daytime drip was then stopped and they were given 2 pints of milk by drip at night only for a further period of 10 days In *part B* the same course was given but sodium bicarbonate was added to the milk In *part C* the alkalinised milk was given day and night for 3 weeks and the period on night drip only was omitted

The Addition of Alkali

The primary object of milk drip treatment is to reduce the acidity of the gastric contents to such a level that the peptic activity of the juice is eliminated over the whole of the 24 hours To be certain of doing this the pH must be raised to a level of about pH 4 In fact, milk given continuously between meals does not generally have this effect, and a considerable amount of alkali has to be added before a satisfactory level can be ensured (see figure) Observations in the medical unit at St Mary's Hospital showed that in patients with gastric ulcer the addition of 20–40 g of sodium bicarbonate to the daily ration of milk was usually sufficient, but that in a few such patients (3/15) a daily dose of 60–160 g was necessary Patients with duodenal ulcer generally required 80–100 g (Price and Sanderson 1955)



pH of the gastric contents during the administration of continuous intragastric milk drip, with and without added sodium bicarbonate

* Data for the presence of pain on admission and for the initial weight are not available for part C of the trial

van Goidsenhoven et al (1954) have shown that, although well marked chemical alkalosis may develop, doses of sodium bicarbonate of this order may safely be given to patients with peptic ulcer for periods of up to 3 weeks, so long as there is no evidence of pyloric stenosis, renal failure, or cardiac failure

The present investigation was started before the work of van Goidsenhoven and his colleagues was completed, and in *part A* milk drip was given alone without the addition of alkali In *parts B and C* a routine dose of 40 g of sodium bicarbonate a day was added to every 6 pints of milk It was realised that this dose would not produce the desired degree of neutralisation in all cases, but it was chosen in order to assess the therapeutic effect of a standard dose which could be given routinely in the absence of facilities for frequent estimation of the pH of the gastric contents In *part C* two patients received larger doses (80 g and 140 g a day) because their pain was not controlled on the smaller doses In *parts B and C* of the investigation patients in whom there was evidence of pyloric stenosis or of important renal disease were considered unsuitable for treatment with the alkalinised drip and were excluded from the trial

Initial Comparability of Patients

In the absence of certain knowledge of the clinical features which affect prognosis (Doll and Pygott 1952, 1954), the only precautions taken to ensure that the patients given the different treatments were comparable before treatment was started were (1) the exclusion from the trial of patients who had been treated previously, and (2) the allocation of the specific methods of treatment for each patient at random The results of treatment have been assessed by recording the change in size of the radiographic ulcer niche, the change in the patient's weight, and the duration of the patient's symptoms The initial comparability of the patients in the different groups with respect to the characteristics immediately relevant to these measures is evident from table I, which shows that

(1) Equal proportions of the patients on drip and not on drip continued to complain of pain on admission (51/72 in each case)

(2) The average initial body weight was somewhat lower in the drip series The effect of this difference is considered later, in the analysis of the results

(3) Rather more of the patients in the control series had very small ulcers (22/72, compared with 17/72) Complete

healing is more likely when the ulcer is small, but an increase in the size of the ulcer is also commoner in small ulcers, so the average amount healed, expressed as a percentage of the initial size, is practically the same as for large ulcers The difference between the initial sizes of the ulcers in the treated and control groups is not great, and it is unlikely to have materially affected the results

Results

The results are summarised in tables II–IV Table II shows, for each of the main groups, the numbers of patients in whom the ulcer had completely or partly healed after a month's treatment and the average amount healed, expressed as a percentage of the initial size of the ulcer, for the whole group In each part of the investigation the proportions of ulcers which healed completely in a month were similar for the patients on milk drip and for the control patients not on milk drip, in all parts taken together the proportions were identical (20/82) In parts B and C of the investigation (in which alkali was added to the milk) the proportions healed by two-thirds or more were also similar (27/42, compared with 28/42), and so were the average amounts healed

TABLE II—PATIENTS GIVEN MILK DRIP AND CORRESPONDING CONTROL PATIENTS RESULTS OF TREATMENT ASSESSED RADIOGRAPHICALLY

Part of trial	Treatment	No of patients	No of patients in whom niche was				Average amount healed (%)
			Healed	Two thirds or more healed	Less than two thirds healed	Larger	
A	Drip	40	10	17	9	4	69 7
	Control	40	9	8	16	7	50 7
B	Drip	32	8	11	13	0	69 5
	Control	32	8	13	9	2	65 8
C	Drip	10	2	6	2	0	80 2
	Control	10	3	4	3	0	82 8
All parts	Drip	82	20	34	24	4	70 9
	Control	82	20	25	28	9	60 5

In part A (in which no alkali was added), on the other hand, more ulcers healed by two thirds or more among the patients on milk drip than among the control patients not on drip (27/40, compared with 17/40) In view of the fact that the difference appears in only one of the three parts of the trial, that the response to the drip in part A was no better than in parts B and C, and that the response to treatment in the control group was appreciably worse than in parts B and C, it seems most likely that the difference was due to an unfortunate play of chance in the selection of patients for the control group[1]

Table III shows the effect of treatment as assessed subjectively by the patients' symptoms in parts A and B of the investigation detailed records were not kept in part C More patients on milk drip were completely free of pain than in the control group not on milk drip (36/72, compared with 25/72), but the difference is not large and could reasonably be attributed to chance ($\chi^2 = 3\ 44$, $n = 1$, $0\ 05 < P < 0\ 10$) The measure of symptomatic relief shown in table III is, however, not a sensitive one and the impression was obtained that pain, when present, became less severe and less frequent *immediately* after the drip was instituted Several patients on drip who complained of pain, complained of it only during the periods when the drip was stopped or when the *drip bottle ran empty* 2 patients in part C of the trial continued to have pain when given the standard milk-alkali mixture The gastric contents in these patients were found to have an acidity below pH 3 5 while they were on the drip, and the amount of alkali was, therefore, increased Freedom from pain was eventually achieved with daily doses of 80 and 140 g

TABLE III—PATIENTS GIVEN MILK DRIP AND CORRESPONDING CONTROL PATIENTS RESULTS OF TREATMENT ASSESSED SYMPTOMATICALLY

Part of trial	Treatment	No of patients	No of patients		
			Pain-free	With occasional pain	With daily pain for a week or longer
A	Drip	40	21	9	10
	Control	40	15	16	9
B	Drip	32	15	14	3
	Control	32	10	15	7
A and B	Drip	72	36	23	13
	Control	72	25	31	16

Patients on the drip tended to gain weight more rapidly than the control patients, this was particularly true of patients on alkalinised drip Weight changes after 1 month's inpatient treatment are shown in table IV Data for 3 patients have been excluded because the presence of major intercurrent disease is likely to have affected them (1 patient on drip in part A with generalised dermatitis and 2 control patients in part A with pulmonary tuberculosis), adequate records for 5 others are missing The differences between the numbers of patients gaining different amounts of weight in the two treatment groups are statistically highly significant (parts A and B taken together, $\chi^2 = 30\ 26$, $n = 3$, $P < 0\ 001$) Gain in weight tended to be greater for patients with a low initial weight, and on the average the patients on drip had a lower initial weight (table I) This, however, cannot have accounted for the results The initial difference between the series is eliminated if the 10 patients who weighed under 7 st are excluded, the average initial weight in both series is then 9 st 2 lb 11 oz, and the average gain in weight is 6 lb 14 oz for the drip series and 3 lb 6 oz for the control The greater gain in weight may have been partly due to water retention, particularly among the patients on alkalinised drip The secondary fall which follows the cessation of treatment with large doses of fluid and alkali was illustrated by van Goidsenhoven et al (1954) In the present investigation, however, the final weight was recorded, not immediately after the period on continuous drip, but at the end of a subsequent period of 10 days during which the drip was confined to 2 pints of milk at night only No records are available for the weight a week or so after all treatment had been stopped, but nearly all patients were weighed (as outpatients) 2–3 months after discharge These outpatient records show that the average increase in weight over the initial inpatient record was still 15 oz more for patients who had been treated with milk drip than for the control series, and 1 lb 5 oz more if patients with an initial weight of under 7 st are excluded These differences are not statistically

TABLE IV—PATIENTS GIVEN MILK DRIP AND CORRESPONDING CONTROL PATIENTS CHANGES IN WEIGHT AFTER ONE MONTH

Part of trial	Treatment	No of patients	No losing weight	No gaining weight			Average gain in weight		No of patients excluded
				0–4 lb	5–9 lb	10 lb +	lb	oz	
A	Drip	38	2	11	20	5	6	13	2
	Control	37	6	21	10	0	2	15	3
B	Drip	30	0	2	17	11	8	6	2
	Control	31	4	10	17	0	4	3	1
A and B	Drip	68	2	13	37	16	7	0	4
	Control	68	10	31	27	0	3	8	4

---

[1] Considered as the results of a single trial, the difference between the proportions 27/40 and 17/40 is statistically significant ($\chi^2 = 5\ 05$, $n = 1$, $P = 0\ 03$) The trial was, however one of a set of three, and in these circumstances the standard level of significance is not appropriate In any set of three trials, one or more will show a difference attributable to chance with a probability of as little as 0 02 once in 20 times, and 0 02 should, therefore be taken as the appropriate level of significance for the results of one of the trials taken alone

significant but, in the absence of more detailed data, it seems reasonable to conclude that some of the increase in weight associated with milk-drip treatment was probably due to an increase in body-tissue [2]

Side effects

The drip treatment was carried out without difficulty The great majority of patients grew accustomed to the presence of the tube after a few hours, and although a few continued to find it unpleasant the discomfort was in no case so great that the treatment had to be abandoned Several patients complained of mild heartburn which they had not noticed previously and which ceased when the tube was removed (In 1 patient, not in the present series, diarrhœa appeared to be produced by the drip and was sufficiently severe to necessitate abandoning the treatment)

In none of the patients on alkalinised drip did renal failure develop, nor were any symptoms observed which could be attributed to alkalosis specifically The biochemical effect of prolonged administration of such large doses of sodium bicarbonate in man is discussed by van Goidsenhoven et al (1954)

Discussion

The failure to demonstrate a beneficial effect on the healing of gastric ulcers with continuous intragastric milk drip is disappointing Even the addition of alkali to the milk in sufficient quantity for the acidity of the gastric contents to be kept, in the majority of patients, above pH 4 throughout the 24 hours failed to have a recognisable influence on the healing process It is, of course, possible that the continuity of the drip was not maintained with the same exacting attention to detail under conditions of routine treatment as in the course of the experimental observations which have been referred to Regular tests of the pH of the gastric contents were not made during the trial, and in some or all of the patients the acidity may occasionally have fallen temporarily to below pH 4 Nevertheless such occasions cannot have been of more than short duration in the majority of the patients in parts B and C of the trial, and it is unlikely that any more complete neutralisation has been achieved in any other reported series It would seem, therefore, that, unless very short periods of exposure are effective, peptic digestion cannot be of prime importance in maintaining the activity of a gastric ulcer and that, under conditions of bed rest in hospital, further treatment aimed at the complete elimination of peptic digestion is unlikely to help the ulcer to heal

It is not suggested that continuous neutralisation does not relieve the pain of peptic ulcer There is good evidence that, when an " active " ulcer is present in the stomach, pain can often be reproduced by instilling an acid fluid, and conversely that pain, when present, can be abolished constantly by withdrawing the gastric contents or by their neutralisation (Palmer 1927, Bonney and Pickering 1946) The present investigation confirms the impression that pain is relieved more readily by a continuous milk drip than by the standard medical regime, and we therefore accept intragastric drip as a useful adjunct to the treatment of those rare cases in which the pain does not respond to rest in bed

The present data throw no light on the value of milk drip in the treatment of duodenal ulcer Acid secretion is usually increased in quantity in patients with a duodenal ulcer, while it is usually close to normal in patients with gastric ulcer (Ihre 1947, James and Pickering 1949) It is, therefore, possible that peptic digestion may play a more important rôle in the production or maintenance of the activity of duodenal ulcers, and conclusions drawn from the treatment of patients with a gastric ulcer cannot be applied automatically to the treatment of patients with a duodenal ulcer

The more rapid gain in weight obtainable with a milk drip may be, in some circumstances a positive indication for its use

Summary

The value of continuous intragastric milk drip in the treatment of gastric ulcers has been investigated by means of a controlled trial which covered 164 inpatients in two hospitals 82 received the drip treatment, and 82, who were otherwise treated in the same way, did not In 40 patients the drip consisted of 6 pints of milk a day without any added alkali, in 40, 40 g of sodium bicarbonate was added to each 6 pints of milk, in 2 the dose was increased to 80 and 140 g

The proportion of ulcers which healed in the course of a month was identical in the two treatment groups (20/82) The average amounts healed, expressed as a percentage of the initial size of the ulcer, were also similar

The impression was received that pain was relieved more rapidly with milk drip than without it, and an alkalinised milk drip is considered a useful adjunct to the standard treatment in patients whose pain persists after rest in bed

Patients given milk drip gained, on the average, more weight than patients not given the drip (7 lb 0 oz, compared with 3 lb 8 oz), and a slight advantage (15 oz) was still preserved 2–3 months after discharge

We are grateful to Dr F Avery Jones and to Prof G Pickering for their advice and for allowing us to treat patients referred to their clinics, and to the staff of the gastro enterological and radiological departments of the Central Middlesex Hospital and of the medical unit and radiological department of St Mary's Hospital for help in the management and examination of the cases One of us (A V P) was working with a grant from St Mary's Hospital research fund

[2] For all cases $t = 0\,88$ $n = 131$, $P > 0\,10$ excluding cases with an initial body weight of under 7 st. $t = 1\,24$, $n = 121$, $P > 0\,10$

CONTINUOUS INTRAGASTRIC MILK DRIP IN THE TREATMENT OF UPPER GASTRO-INTESTINAL HÆMORRHAGE

A M DAWSON
M.B Lond, M.R C P
FORMERLY HOUSE-PHYSICIAN, GASTRO ENTEROLOGICAL UNIT, CENTRAL MIDDLESEX HOSPITAL, LONDON

FURTHER hæmorrhage in patients who are being treated in hospital for hæmatemesis and melæna is a danger signal A continuous intragastric milk-drip has been claimed to hasten the healing of peptic ulcer (Winkelstein 1949) An indwelling Ryle's tube has been recommended in the management of upper gastro-intestinal hæmorrhage to facilitate the early diagnosis of re-bleeding (Chandler and Watkinson 1953) If either of these suggestions is well founded deaths from hæmatemesis and melæna might be prevented These suggestions have been tested in a study described here

Material and Method

In a series of 100 consecutive cases of gastro-intestinal hæmorrhage a Ryle's tube was passed to between marks

TABLE I—DISTRIBUTION OF CASES BY DIAGNOSIS AND AGE GROUP

—	Milk drip (50 cases)	No milk drip (50 cases)
Diagnosis		
Duodenal ulcer	18	18
Gastric ulcer	8	8
X ray neg	16	17
Postop and miscellaneous	8	7
Age group (yr)		
<50	21	21
50–69	17	22
70 +	12	7

II and III Alternate patients were treated with a continuous intragastric milk drip of 6 pints of non citrated milk each 24 *hours*, no sodium bicarbonate was added to the milk Otherwise the patients were treated routinely by a puree diet, alkalis for symptomatic relief of pain sedation, blood replacement, and emergency operation if necessary 3 patients, all aged 70 years, would not tolerate the tube The following data were charted for 72 hours results of hourly aspirations of the stomach, pulse-rate each hour, blood-pressure every 4 hours, and presence of shock, pallor, or overt bleeding

Results

The final diagnosis and the distribution of cases by age groups were used as criteria for assessing the comparability of the two groups (table I) There was a remarkably even distribution, except for slight weighting of the milk-drip series by a greater number of patients over 70 years of age

The value of a milk drip was assessed by comparing in the two groups the number of deaths, the number of massive further hæmorrhages as shown by alteration in the pulse-rate and blood-pressure, sweating, and overt hæmorrhage, the number of patients requiring emergency operation, and the number of patients in whom fresh blood was aspirated *after previous aspirations* that were clear or contained altered blood and in whom no other signs of hæmorrhage were noted ("tube re-bleeding") The results are shown in table II

There is no significant difference between the results obtained in the two groups In only 1 case did aspiration give warning of massive hæmorrhage, and this was 45 minutes before other signs appeared In all other patients signs developed simultaneously with the aspiration of blood In 10 patients mild re bleeding, as shown by aspirations, occurred in the absence of massive re bleeding

TABLE II—DEATHS, MASSIVE FURTHER HÆMORRHAGES, EMERGENCY OPERATIONS, AND "TUBE RE BLEEDING"

—	Milk drip (50 cases)	No milk drip (50 cases)
Death	5	3
Massive further hæmorrhage	12	16
Emergency operation	7	4
"Tube re bleeding"	2	8

Discussion

There is no evidence that a milk drip prevents recurrence of massive hæmorrhage The series described by Ashby and Whitehouse (1955) suggested that a milk drip tends to diminish the duration of bleeding, but the evidence is open to criticism since a retrospective control group was used Ashby and Whitehouse claimed "early reassurance, confidence and freedom from shock" among patients treated with a milk drip, but this is not substantiated by the present series

I have not found an indwelling Ryle's tube of value in giving warning of impending massive hæmorrhage after admission If note had been taken of tube re bleeding in this series there would have been many false alarms It seems that massive re bleeding usually occurs suddenly

It has been suggested that a Ryle's tube might be useful in keeping the stomach empty of blood, but it does not have this effect after massive hæmorrhage, as anyone will agree who has attended an emergency partial gastrectomy and seen the large amount of clot which has to be evacuated from a dilated stomach Even a large stomach-tube or duodenal tube has proved inadequate in such cases

Summary

100 cases of upper gastro intestinal hæmorrhage were managed with an indwelling Ryle's tube

Alternate cases were treated with a continuous intra gastric milk drip

The two groups were found to be well matched for age and cause of bleeding

The two groups did not differ in the incidence of massive further hæmorrhage

An indwelling Ryle's tube is of little value in giving warning of an impending further massive hæmorrhage

I thank Dr F Avery Jones for his encouragement and advice

THE ÆTIOLOGY OF CLEFT VERTEBRAL ARCH IN SPONDYLOLISTHESIS

JOHN MUTCH

LECTURER IN ANATOMY

ROBERT WALMSLEY
M.D Edin, F R C S E, F R S E
BUTE PROFESSOR OF ANATOMY

UNIVERSITY OF ST ANDREWS

THE term "spondylolisthesis," in its wider sense, embraces all conditions in which the body of a lower lumbar vertebra, with or without an intact vertebral (neural) *arch, is displaced forwards on the succeeding* vertebra The term thus used is not strictly in accordance with its literal meaning—i e, "slipping vertebra" It was introduced by Kilian (1854) to denote a displacement forwards of the entire fifth lumbar vertebra

Lambl (1858) described some cases of spondylolisthesis in which there was a breach in the bony continuity of the vertebral arch between the superior and inferior articular processes, and this part of the arch he appropriately called the pars interarticularis In such cases of spondylolisthesis the body of the vertebra carries forward with it the pedicle, the transverse process, and the superior articular processes, while the inferior articular process, the lamina, and the spinous process remain in situ

Most Continental workers now accept this bone lesion of the arch as an essential feature of spondylolisthesis, whereas English speaking workers prefer the *more comprehensive application of the term* It is in accordance with such an interpretation of spondylolisthesis that Newman (1955), in an analysis of 204 personal cases, remarks that only about half of them showed a breach in the arch

The present non *clinical contribution to the literature* of spondylolisthesis is concerned only with those cases in which there is a cleft in the vertebral arch, and it is submitted as additional evidence that such a lesion, when present, does not result from a failure of *fusion* between two centres of *ossification This hypothesis* has in the past received considerable support and appears to stem from the claims of Schwegel (1859) and Rombaud and Renault (1864) that there are double ossific centres in each half-arch Various other workers have supported the idea of double centres, but no convincing evidence for them has ever been advanced

All critical observations have substantiated the view that a cleft in the pars interarticularis is the result of fracture of an ossified arch

Rowe and Roche (1953) have produced convincing evidence in support of this assertion in an analysis of 509 stillborn and neonatal cadavers (73 of their own and the remainder previously published) they did not find a single instance of a breach in the bony continuity of the vertebral arch, although in adults the generally accepted figure of such a breach in the arch of the fifth lumbar vertebra is about 5% Their analysis also showed that the 5% prevalence is attained by the twentieth year and thereafter remains fairly constant

Stewart (1953), however, reports from the examination of 786 skeletons of Alaskan natives that there is in them an increase in the incidence of the defect during adult life, and he believes that this is mainly due to the combination of unusual postural stresses and a high accident rate

We believed that a study of ossification in the vertebral arch might contribute towards a solution of the ætiology of a cleft in the pars interarticularis , and, since spondylolisthesis is restricted to the lumber region, the observations recorded here are limited to that part of the vertebral column

The critical stages in the early ossification of the vertebral arches of the lumbar vertebræ are while the fœtus increases in its crown-rump length from 75 mm to 130 mm Our observations were made on serial sections of seven fœtuses between these lengths, and to clarify the exact position of the ossific process three reconstructions were made Observations were also made on other younger and older specimens to verify certain findings

Observations

In each half of the vertebral arch a well-marked sequence of changes take place which are always most advanced in the first lumbar vertebra and least so in the fifth vertebra in any one fœtus The pattern of ossification in the arch of the fifth lumbar vertebra differs in no way from that in the arch of any other lumbar vertebra The vertebral arch of the fifth lumbar vertebra in a fœtus about 70 mm long is formed of cartilage, but by the 75-mm stage a small region of the cartilage in the anteromedial part of the pars interarticularis has become calcified At this stage the cartilage of the vertebral arch is avascular and in this feature differs from the bodies of the vertebræ, which show numerous vascular canals before ossification. These canals show as clear spaces in the bodies of the vertebræ seen in fig 1 The calcification in the arch is indicated, in sections stained with hæmatoxylin and eosin, by the deep purple of the intercellular matrix and by an increase in size of the lacunæ containing the cartilage cells, whose cytoplasm has become swollen and vacuolated

After this localised calcification has taken place, a thin lamina of subperiosteal bone is laid down on the anteromedial aspect of the pars interarticularis directly overlying the calcified cartilage in a manner that is essentially similar to the first deposition of bone in the shaft of a long bone Thereafter the calcified cartilage is invaded by blood-vessels and partly destroyed and excavated With increase in size calcification of the matrix extends in all directions from its initial focus, upwards and downwards into the roots of the articular processes, forwards into the pedicle, and backwards and laterally towards the posterior and lateral aspects of the pars interarticularis, and gradually reaches the perichondrium in these regions Wherever the calcification reaches the surface of the cartilage the perichondrium assumes an osteogenetic function, and subperiosteal bone is deposited

The sequence of this process may be seen, in some measure at least, in a single sagittal section of the lumbar vertebræ of a 101 mm fœtus (figs 1 and 2) This section passes through the lateral part of the body of each vertebra, the pedicle, the superior and inferior articular processes, and the pars interarticularis The process of ossification has just begun on the anterior aspect of the

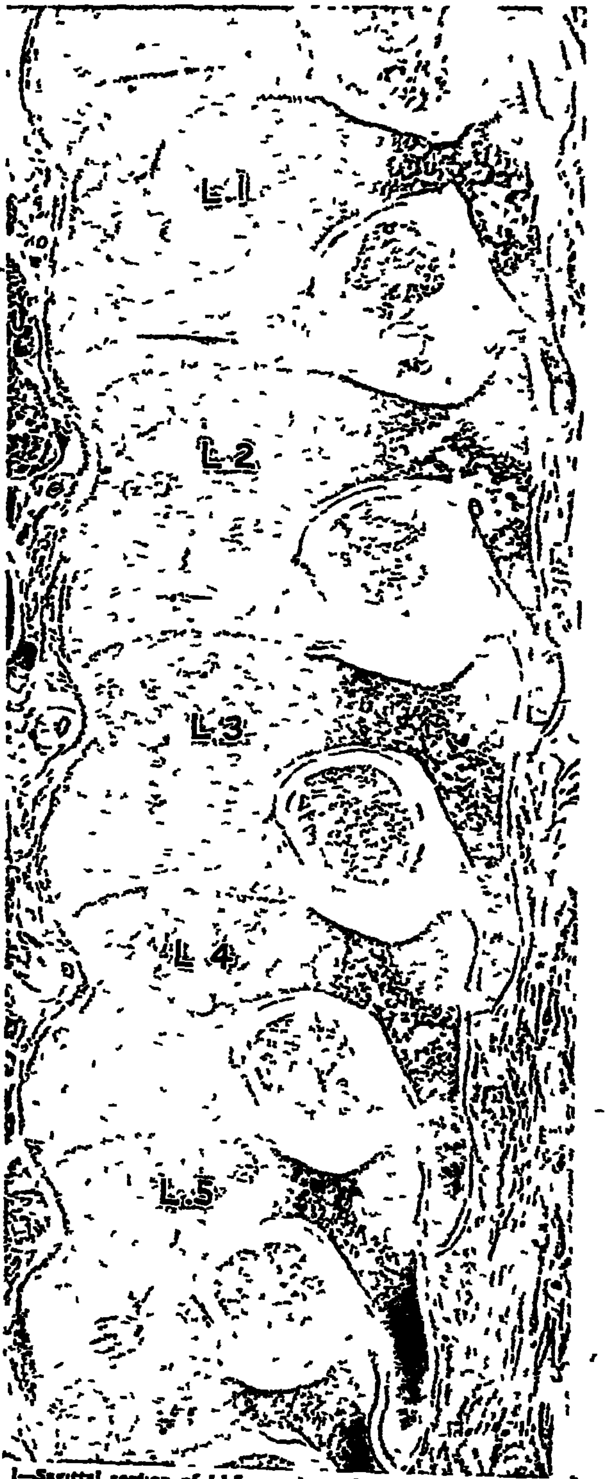

Fig 1—Sagittal section of L1-5 vertebræ of 101 mm (crown-rump) fœtus through bodies pedicles, superior and inferior articular processes, and pars interarticularis Ossification is most advanced in L1 vertebra and least in L5 (×10)

pars interarticularis of the fifth lumbar vertebra, where the bone is seen as a dark lamina lying in front of the calcified cartilage (fig 2c) In the first lumbar vertebra the process of ossification is much more advanced, and the lamina of bone has circumscribed the pars interarticularis, therefore in a sagittal section (fig 2a) bone is seen on both the front and the back of this region While *the deposition of subperiosteal* bone continues, there is massive excavation of the central cartilage of the pars interarticularis (fig 2*a*), and this is as characteristic *a feature of ossification of the* vertebral arches as it is of ossification of the diaphysis of a long bone Small islets of calcified cartilage remain, however, within the subperiosteal collar of bone, and upon these the primary medullary bone of the trabeculæ is laid down

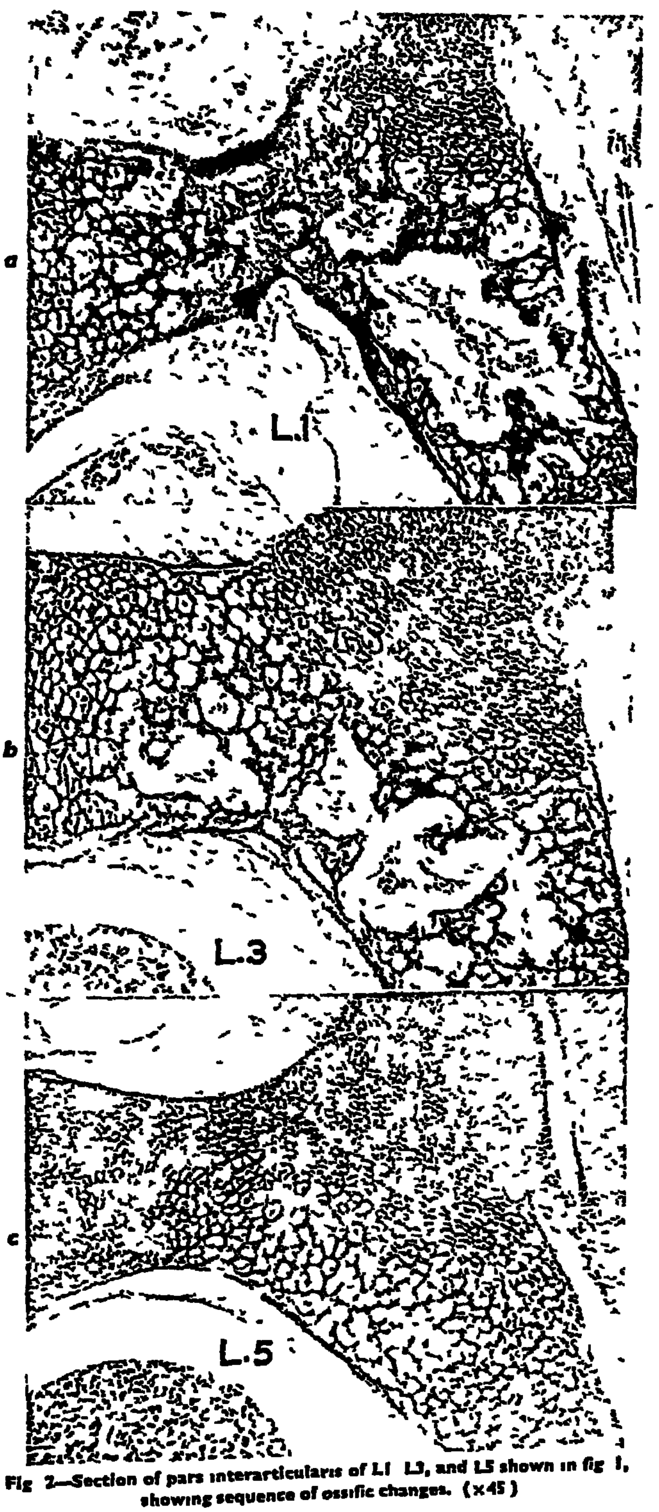

Fig 2—Section of pars interarticularis of L1 L3, and L5 shown in fig 1, showing sequence of ossific changes. (×45)

Reconstructions of lumbar vertebræ of three fœtuses (75 mm, 93 mm, and 101 mm long) show that the calcified cartilage, along with the first-formed bone in the pars interarticularis, together constitute a hemispherical mass This is contradictory to the finding of Willis (1931), who states that the single centre is shaped like an hour glass, a form which, he suggests, may have given the impression to some workers that there are two separate centres in the arch

By the time the fœtus has grown to a crown rump length of about 130 mm the ossification in the vertebral arch of the fifth lumbar vertebra has reached a stage comparable *to that of the first vertebra in the 101 mm* specimen (fig 2*a*) The pars interarticularis is represented by a relatively thin shell of compact bone through which pass numerous vessels Within the primitive medullary cavity are islets of calcified cartilage on which bone is being deposited

Sections through the pars interarticularis of older fœtal and postnatal vertebræ show great variations in the thickness of the cortical bone and in the density of the medullary trabeculæ in specimens of about the same age

Conclusions

Our observations indicate that ossification in a vertebral arch closely resembles ossification in the diaphysis of a long bone In both of them calcification of the cartilaginous matrix is followed by deposition of bone at the surface immediately beneath the periosteum, but only where calcified cartilage has come into apposition with the perichondrium Thereafter ossification continues by thickening and extension of this subperiosteal bone, while the calcified cartilage enclosed and supported by this shell of bone is gradually removed The bone of the medullary trabeculæ is, in the first instance, laid down on the small islets of calcified cartilage that temporarily persist The one difference is that in a long bone the calcification of the matrix begins within the central part of the diaphysis, whereas in the vertebral arch it begins eccentrically on the anteromedial aspect of the pars interarticularis

This pattern is opposed to endochondral ossification as typically seen when a secondary centre or centres of ossification appear within the cartilaginous end of a long bone to constitute an epiphysis There one, two, or more ossific centres may appear within the substance of the cartilage, but there is no primary formation of surface bone as has been described in the ossification of the vertebral arch, nor can there be an accompanying massive destruction of the cartilage within a well defined primary bony collar

These observations are in striking contrast to the statements of Hitchcock *(1940) referring to ossification* of the vertebral arch "This (the ossification) is preceded as in all endochondral ossification elsewhere by the invasion of vessels *from the laminar arteries*" and "The periphery of the isthmic (interarticular) region remains cartilaginous up to and after birth"

As long as Bardeen's (1910) statement is perpetuated that ossification in the vertebral arch is endochondral, and his figure (after Quain), showing this ossification within the substance of the cartilage of the arch, continues to be reproduced, so too will there be misapprehension about possible anomalies in the neural arch Bardeen's statement *that sometimes in the fifth lumbar* vertebra there are two centres for the arch (for which he gives no authority) is in our opinion inconsistent with the manner in which the arch is ossified

All our observations confirm that the whole pars interarticularis is involved in the sequence of changes which take place, and that the process extends from its initial focus in the pars interarticularis to include the whole of the corresponding half of the vertebral arch Furthermore, the bone is laid down as a continuous layer beneath the periosteum wherever calcification of the cartilaginous matrix has extended as far peripherally as the perichondrium Friberg (1939), in photographs of reconstructions of fœtal vertebræ, shows that the first-formed bone is on the anteromedial aspect of the pars interarticularis, in a site almost identical with that which we have observed in our specimens Friberg did not, however, refer to subperiosteal deposition of the first bone, nor did he draw what we believe to be important and pertinent conclusions from it This formation of surface bone is accompanied by such a massive destruction of the underlying cartilage that to postulate that either one or two primary ossific centres appear in this very cartilage is tantamount to assuming that the pattern of ossification is different from that which has appeared so constantly in all our sections and bears a close resemblance to the ossification shown by Friberg (1939) in photomicrographs of fœtal vertebræ

This pattern of ossification is basically opposed to the appearance of either single or double primary endochondral ossific centres within the vertebral arch, and this in turn is in full accordance with the failure of Rowe and Roche (1953) to discover a single instance of cleft vertebral arch in over 500 stillborn and neonatal cadavers If a cleft vertebral arch is caused by a congenital factor, we believe that *it is not due to two centres of ossification but to weakness in the bone of the pars interarticularis of the vertebral arch*

Summary

The pattern of ossification in the vertebral arch of the *fifth lumbar vertebra is similar to that in the arches of* other vertebræ

The site of the initial ossification in the vertebral arch of the fifth lumbar vertebra is indicated by the calcification of the cartilage in the anteromedial part of the pars interarticularis

The bone is first deposited subperiosteally and gradually forms a collar round the pars interarticularis

The laying down of subperiosteal bone is accompanied by much excavation of the underlying calcified cartilage

Ossification in the vertebral arch is not endochondral and *does not appear to be consistent with double ossific* centres

Our sincere thanks are due to Mr J Brown, of this department, for the microscopic sections and photographs

“ If men value their liberty they are well advised to understand the customs and institutions in which it is grounded and they must be vigilant in its defence But, though recognising it to be above price, they should no more make a fetish of it than a wise man does of his health He learns the principles of hygiene, takes reasonable precautions against abuse, and then gets on with the important things of life which his health permits him to pursue ”—*The Times*, Dec 28, 1955, p 7

THE GENESIS OF THYROID ADENOMAS

HERMANN ZONDEK
M.D Berlin
VISITING PROFESSOR OF MEDICINE IN THE HEBREW UNIVERSITY OF JERUSALEM

H LESZYNSKY
M.D Berne
CLINICAL ASSISTANT

From the Bicur Cholim Hospital, Jerusalem

IT is generally accepted that both diffuse and nodular enlargements of the thyroid gland are ultimately due to alterations in the secretion or the activation of the thyrotropic hormone, no matter whether the primary cause is a goitrogenic agent, lack of goitre-preventing factors, or another, unknown, source of deficient synthesis of thyroid hormone (“ inborn error of metabolism ” of Hutchison and McGirr 1954)

Why, in one and the same gland, the increase tends to be *local rather than uniform is not* understood For this reason we investigated the underlying conditions in hypothyroid goitres

Material

The subjects of the study were two siblings, a boy aged 17 years (case 1) and his sister aged 12 (case 2), with familial sporadic cretinism and goitre, who have been reported in detail elsewhere (Zondek et al 1955)

Both had very voluminous diffuse goitres in which five (case 1) and three (case 2) nodules, varying in size from that of large cherries to that of peaches were embedded, and both showed the clinical picture of childhood myxœdema

The administration of a total dose of 960 µg (case 1) and 820 µg (case 2) of tri iodothyronine within eight and nine days respectively led to the disappearance of the myxœdema The response *of the goitres to therapy was, in both patients,* consistent with the well known fact that diffuse thyroid enlargements respond more readily than nodular ones in case 1 reduction of the total volume of the thyroid gland was *first noted after 240 µg (two days) and in case 2 after 80 µg* (one day) of tri-iodothyronine, and the nodules started to decrease after *360 µg (three days) and 520 µg* (six days) respectively

Subsequently there was in both patients a striking decrease of the diffuse and nodular areas alike In case 1 three of the five nodules were no longer palpable after 840 µg of tri-iodothyronine (seven days), the fourth disappeared later under treatment with thyroid gland (7 g in ten weeks), but the fifth, which at that time had shrunk to the size of a small hazelnut, subsequently remained stationary despite prolonged intensive treatment with thyroid The three nodules in case 2 considerably decreased in size during treatment with tri iodothyronine and, later, thyroid but, like the fifth nodule of case 1, did not disappear completely

Present Investigation

After a state of clinical remission had been maintained for some time, both patients were allowed to relapse so that we might possibly find out how the release of the goitrogenic agent from the suppressive action of thyroid hormone would affect the structure of the thyroid gland

Results

In case 1 a clinical relapse was accompanied by renewed and rather rapid formation of a goitre, which again was partly diffuse and partly nodular Diffuse enlargement seemed to precede the formation of the nodules Four nodules reappeared in the converse order of their disappearance They occupied exactly the same sites as before treatment with thyroid Their size had nothing to do with the rate and intensity of either their regression or their reappearance All the nodules, including the fifth, which had never entirely disappeared, attained their former size within sixty nine days after the withdrawal of therapy Repeated administration of thyroid produced a response identical with that produced in the first therapeutic trial Along with clinical remission the four nodules in the same sites as those that disappeared under treatment with tri-iodothyronine and, later, thyroid again disappeared completely, so far as could be ascertained by careful palpation The fifth nodule also behaved in the same manner as the one in the same site in the first therapeutic period although reduced to the size of a hazelnut it did not disappear even after prolonged treatment with thyroid gland and was subsequently removed surgically Histological examination (Dr H Ungar, of the Hadassah Medical School) showed a typical colloid adenoma surrounded by a thick fibrous capsule There was no fibrosis or calcification within the adenoma tissue which might have accounted for its resistance to therapy

In case 2 withdrawal of therapy caused both the diffuse and the nodular parts of the goitre to enlarge progressively Renewed administration of thyroid produced considerable regression of the nodules, which, however, exactly as in the first therapeutic trial, did not subside entirely One of them was removed and also showed the structural properties of a colloid adenoma, again without degenerative changes (Dr Ungar)

Radio-iodine studies during the first period of observation showed in case 1 a total uptake of 14 3% by the thyroid gland after forty eight hours Nodular and diffuse areas behaved exactly alike, except that one nodule collected two or three times as much iodine as did the other tissues (Dr A Hochman, of the Hadassah Medical School) The more active nodule was one of the four which had completely regressed under treatment with thyroid—in other words, it responded to therapy and to its subsequent withdrawal exactly in the same manner as did the less active nodules Conversely, the nodule which did not respond completely to therapy showed the same functional behaviour as the nodules which did respond

Conclusions

On the strength of these observations we postulated that in case 1 the regression of the thyroid adenomas under treatment with thyroid was independent of their functional state Rather must we assume that local differences in responsiveness to the goitrogenic agent—presumably the thyrotropic hormone—accounted for the formation, size, and possibly the nature of the nodules Similar reasoning appears to apply to case 2, in which the nodules did not disappear completely even after prolonged and intensive treatment with thyroid It seems that a regional increase in sensitivity to the goitrogenic stimulus may go so far as to render the tissue refractory to even large doses of thyroid hormone, whereas in other areas of the same gland much smaller amounts suffice to counteract the stimulating agent

According to the peripheral theory of Zondek (1924) the quality and intensity of hormonal activity is modified by the state of responsiveness of the peripheral target-organs, in which respect the electrolytic conditions of the cell surfaces were assumed to play an important part (Zondek and Reiter 1923, Zondek and Ucko 1924–26) This conception apparently also holds good for endocrine structures in so far as they represent hormonal target-organs

Two questions have not yet been answered (1) will it be possible to discover the nature of those inherent factors which determine the local responsiveness of the thyroid tissue to the goitrogenic stimuli? and (2) may the administration of thyroid substances which suppress the goitrogenic stimuli succeed not only in reducing the volume of nodules but also in protecting them from disorderly growth—i e, malignant degeneration? On the strength of our observations this hypothesis is advanced first of all for adenomas within hypothyroid glands, but it may also apply to euthyroid (non-toxic) adenomas Our deduction is consistent with the results of experimental and isolated clinical observations to the effect that the administration of anti-thyroid drugs may produce, especially under hypothyroid conditions, malignant, even metastasising, thyroid neoplasms (Griesbach et al 1945, Purves and Griesbach 1947, Money and Rawson 1947, Fodor et al 1948, Bielchowsky et al. 1949, Herrmann 1951, Boulet et al 1953)

"OEDÈME BLEU"

IDA MACALPINE

M D Erlangen, L R C P E

ASSOCIATE CHIEF ASSISTANT IN PSYCHIATRY, DEPARTMENT OF DERMATOLOGY, ST BARTHOLOMEW'S HOSPITAL, LONDON

SIR JAMES PATERSON ROSS

K C V O, M S Lond, F R C S, F A C S

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON, AT ST BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE

> "I likewise saw a man who could not move his hand, it being to his thinking dead".
>
> VALENTINE GREATRAKS, 1666

WE draw attention here to Charcot's *oedeme bleu des hysteriques*, a not uncommon form of "hysterical" affection of joints simulating medical or surgical disease, which is rarely mentioned nowadays in published reports We describe two cases (one following injury), neither of which had been recognised They had been referred to one of us (J P R) with a view to sympathectomy or amputation

Charcot (1890) observed that this disorder is characterised by non-pitting œdema, coldness, purplish discoloration, altered sensation, often total anæsthesia, paresis, and contracture of either hand or foot (fig 1), electrical reactions remain normal He and Pierre Marie (1892) added "trophic derangements among them blister like eruptions" Pain is sometimes, but not always, a feature

Although known by Charcot's name, Brodie (1837) had previously referred to "several cases of this singular affection of the hand and wrist," and Paget (1873) had given a detailed description of it as an example of "nervous mimicry" of organic disease

Hysteria and Hysterical

It is impossible to discuss *oedème bleu des hystériques* without glancing at the history of the term "hysterical" This term has impeded the understanding of mental disorders from earliest times It was once used synonymously with insanity in general, and for "fits" of every kind, and latterly it has been used for somatic symptoms of psychological origin Yet it has resisted all attempts at elimination

> "*The name hysteria should be abolished For it is absurdly* derived and used as a term of reproach, is worse than absurd hysterical is taken by many people that she is silly, shamming, *or could get well if she pleased* call them anything but hysterical" (Paget 1873)

Reynolds (1872) pointed out that "hysterical" meant widely differing things to different people

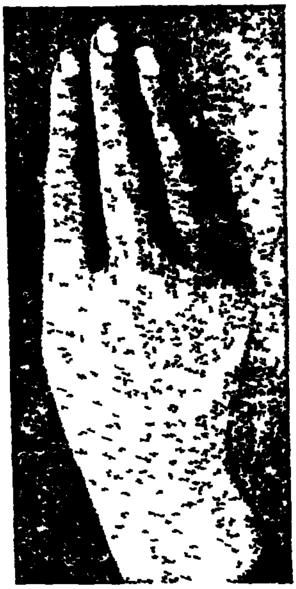

Fig 1—Charcot's original illustration

"'nervous temperament' a mood or disposition of disordered function which cannot conveniently be placed elsewhere simply conveys a doubt as to what is the matter a prevailing conviction that it is nothing very serious"

Allbutt (1869) was "quite sure that by the use of the word hysteria, the medical man not only injured the patient, but damaged his own power to cure"

Unfortunately Charcot elevated hysteria to a disease entity and assembled under *la grande hysterie* a medley of neurological and psychiatric conditions, including epilepsy, hemiplegia, catatonic schizophrenia, malingering, and even fraud He also introduced the misleading factor of hypnotic suggestibility as the hallmark of hysteria

Pathology and Psychopathology

Babinski, in a series of publications in one of which (1896) he described the plantar reflex, demolished Charcot's "hysteria" by demonstrating that lack of diagnostic precision was responsible for purely neurological conditions being termed hysterical But he accepted Charcot's idea that hysteria was due to suggestion, hence only body function subservient to the will could be considered hysterical In a comprehensive survey, he and Froment (1918) suggested calling autonomic symptoms such as œdema "reflex neuroses" in order to emphasise their independent, organic origin, although they agreed that these "reflex neuroses" were usually associated with disturbances of voluntary function, such as paresis, and cleared up with psychotherapy

Roussy and Lhermitte (1918) give the most acceptable explanation of vasomotor and trophic changes found in cases of *oedème bleu*

> "Vasomotor symptoms, fall of the temperature, cyanosis of the paralysed extremities, hyperidrosis, œdema, etc, are the result of functional inactivity, as is proved by their rapid disappearance, when an hysterical paralysis or contracture is cured by psychotherapy"

Today, because we still do not understand how the mind produces somatic symptoms, we are inclined to disregard mental factors Reynolds (1869) had rightly predicted that, if their psychological origin is ignored, such conditions "are theoretically driven into the sympathetic corner, whereas there is nothing to prove that the vaso-motor or sympathetic system is primarily at fault"

Paradoxically, the advent of psychiatry as a specialty in its own right has encouraged this trend, whereas in the past surgeons and physicians dealt with both the body and the mind of their patients, and made valuable psychological contributions, they now leave everything concerning the mind to psychiatrists But the most skilful part—diagnosis and selection of patients—remains their responsibility The psychiatrist labours under similar difficulties he has not the clinical opportunity of comparing organic with non-organic symptoms, and as his training centres largely on mental phenomena, he is ill equipped to deal with patients whose symptoms masquerade as bodily disease Thus patients with somatic symptoms of psychological origin often fall between two stools

Case-reports

Case 1 —A woman, aged 22, shop assistant Left arm in sling, forearm and hand much swollen, skin purplish red, tight, shiny, with several deep ulcers (fig 2A), movement and sensation uniformly reduced, severe pain at times, reflexes, electrical reactions, radiographs, arteriogram, phlebogram, and lymph flow normal

History —Aged 2 adopted by mother's sister, disturbed childhood temper trantrums and sleepwalking In 1946, aged 15, after playing in snow warmed hands in front of fire Both hands red and tight, left appeared swollen Sent to doctor, treated with penicillin and hot bathing Swelling gradually increased, spread up forearm, skin discoloured, ulcers appeared on extensor surface In 1948 admitted to hospital for seven weeks, arm in plaster, penicillin injections Discharged unimproved, outpatient physiotherapy for several months Condition deteriorated

In 1949 referred to one of us (J P R) regarding advisability of sympathectomy or amputation Transferred to psychiatrist (I M) as hysterical paresis

Treatment and progress —Seen eighteen times in eight months Hostile to psychiatric approach "It is not imagination," "I have only been sent for consent to amputation," "Why should I have had so much treatment, if nothing is wrong with my arm?" Clamoured for amputation, complained limb was ugly and disfiguring, but unconcerned about loss of function Bitter about adoption, hostile towards mother who had kept brother "If I had a child I would not get rid of it" Heard of adoption from other children when aged 3, remembers being unable to believe or understand it Consciously devoted to foster-mother, although she was strict, fussy, and possessive During psychotherapy realised she was longing for own mother, whom she called aunt "Perhaps I don't know all the circumstances of the adoption" Wondered whether foster mother had turned her against own mother, accused her of holding on to her Her confused feelings and insecurity were expressed in a recurrent dream she was

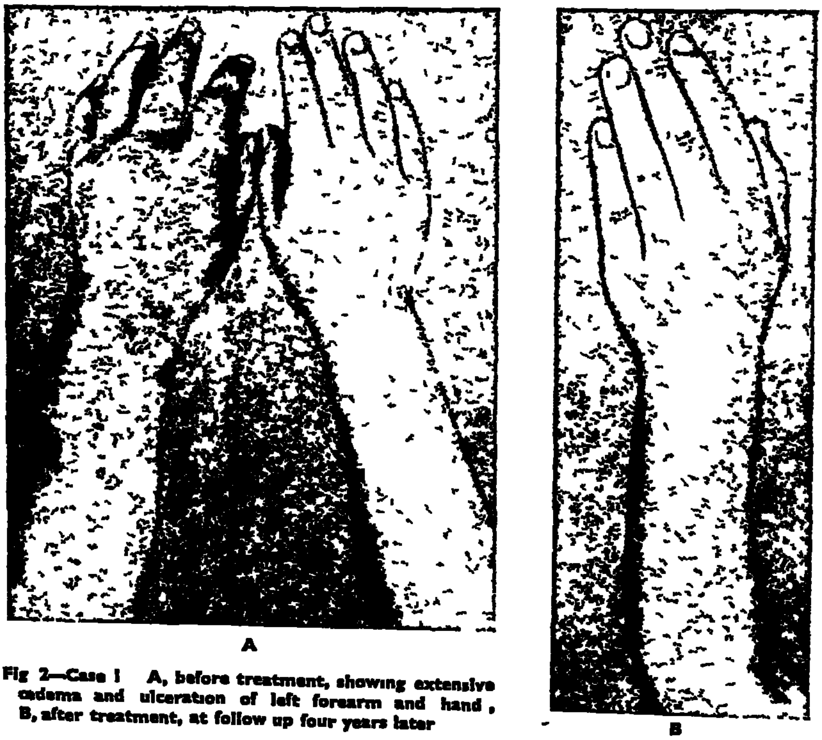

Fig 2—Case 1 A, before treatment, showing extensive œdema and ulceration of left forearm and hand, B, after treatment, at follow up four years later

going to a funeral of either mother or foster mother , she could never tell which Referring to her " two mothers," she said " if only I could cut myself off from this eternal muddle " Later used the same words about her arm, which she wanted " cut off " When it was pointed out that she wished to do with the arm what she had not achieved with her family background, the arm greatly improved , sling and bandage were discarded, colour became normal, ulcers started healing Four weeks later hand entirely normal , full movement, no pain Treatment concluded after two more sessions Four years later working happily as typist, arm and hand remained perfectly normal (fig 2B)

Case 2.—A girl, aged 20, student teacher Loss of movement and sensation in right hand to 2 inches above wrist, contracted, bandaged, and in palmar splint , swollen, reddish blue Reflexes, radiographs, electrical reactions, arteriogram, phlebogram, lymph flow normal

Family and personal history —Father 1914–18 war pensioner, capable only of light work, involved in road accident shortly after patient's accident, with subsequent severe depression Mother handicapped by claustrophobia Patient's early ambition was to teach handicapped children

Present complaint —March, 1952, at college, glass tubing accidentally pierced right hand in mid palm between third and fourth metacarpals Hand bandaged in hospital Because of " pulling sensation " wound explored two days later , no glass found Wound healed " My hand was perfectly all right and I had all sensation, even played netball for about six weeks after accident " May , 1952, hand swelled painlessly, loss of movement index and middle fingers June, 1952, exploration under general anæsthesia several small pieces of glass said to have been removed No improvement In next twelve months four further surgical explorations Patient was told that accident could have been much worse and lucky to have hand at all July, 1953, presented at third hospital with pain and weakness of hand, contracture of fingers, loss of sensation in third and fourth fingers Intensive physiotherapy, but active movement further diminished. Advised to stop using hand altogether, bandage, and use sling while awaiting sixth exploration December, 1953, scar excised, flexor tendons freed from adhesions Slight short lived improvement April, 1954, had to leave training college " in case something happened to my hand " May, 1954, loss of sensation spread to second finger Neurosurgical opinion permanent disability certain, advised to keep hand bandaged to avoid injury Physiotherapy continued, but further deterioration August, 1954, whole hand insensitive, movement grossly restricted, fingers contracted, bluish red (fig 3A) October, 1954, referred to one of us (J P R) for opinion re sympathectomy , referred for psychiatric investigation (I M)

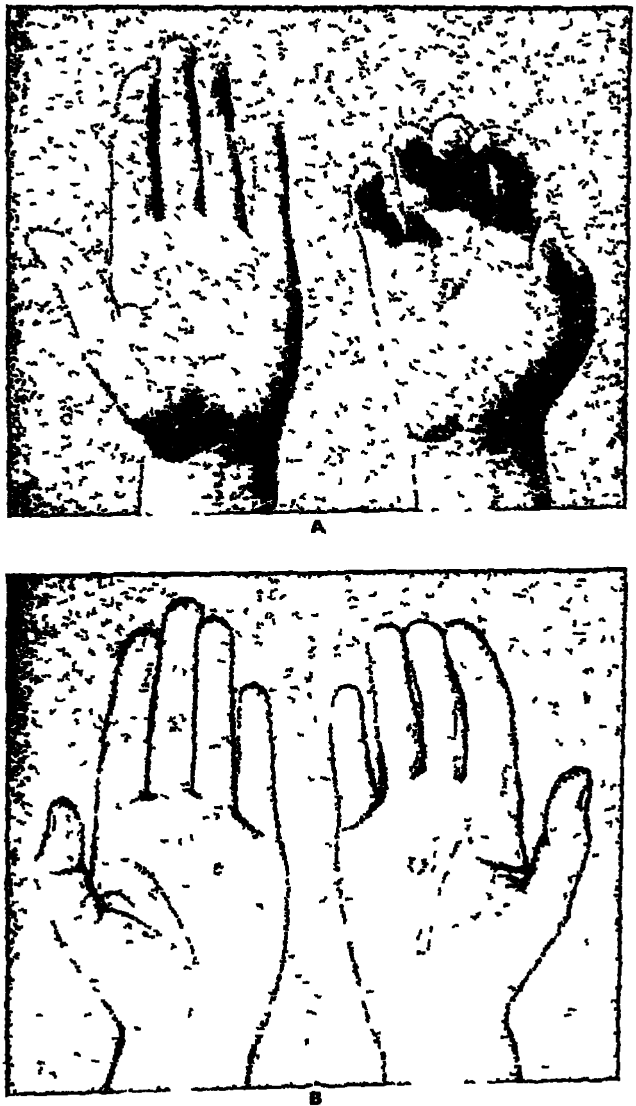

Fig 3—Case 2 A, before treatment, showing swelling and contracture of right hand and scars of injury and operation , B, after five psychotherapeutic interviews

Treatment and progress —Superficially cooperative, but hostile " It is not imagination " Puzzled that surgery, exercises, and physiotherapy had made her worse Believed this confirmed seriousness of original injury " probably it is gangrene " It was explained that the mind can produce somatic symptoms without their being put on or imagined, that attention focused on hand, whether by exercises or bandaging, interferes with normal automatic movement and sensation She wished for amputation " I am almost better without the arm, I could then forget about the accident and all the bother ", " the hand is dead anyway ", " I could get a better job as a severely disabled person " Shock of the accident discussed, and what she thought had happened, also emotional attitude to parents, particularly her intense sympathy with disabled father Advised to discontinue bandaging and sling and to make no conscious effort Later on attempts were made to revive interest in her future and ambition to become a teacher Little direct reference made to arm After third fortnightly interview swelling subsided, movement freer, extension of fingers almost complete, sensation returned except in third and fourth fingers At fifth interview she reported that she found herself using the hand in all activities (fig 3B) Applied for training as occupational therapist and was accepted " as she appeared to have full use of her hand and a firm grip " Relapse ninth interview using hand less coincident with appearing before a committee considering compensation for original injury on sympathetic grounds, negligence having previously been denied Since then improved again, though not prepared to start training till claim settled

Discussion

Differential Diagnosis

Oedème bleu must be differentiated from medical and surgical diseases of joints, central and peripheral nervous disease, dermatitis artefacta, local malignancy, adiposis dolorosa, and peripheral vascular disease

Customarily psychological origin of somatic symptoms is diagnosed only after exclusion of organic disease It is not sufficiently realised that a diagnosis of psychological origin can be made on positive clinical evidence Such cases are by no means uncommon Brodie (1837) found that " at least four fifths of the female patients among the higher classes who are supposed to labour under diseases of the joints, labour under hysteria and nothing else "—a statement endorsed by Paget (1873) and enlarged by Skey (1867) to include " a large proportion of the lower , for much of my practice has been obtained from the wards of St Bartholomew s Hospital "

A carefully recorded history often gives the clue, as when patients have, or have had, other psychosomatic symptoms Cases following minor injuries (e g , the present case 2) commonly have a " latent period " before symptoms appear (Brodie 1837, Horsley 1809) , Turner (1918) spoke of a " phase of incubation " Casual medical remarks often aggravate the condition case 2, when told that she was lucky to have her hand at all, soon lost all power in it , when told she must accept loss of sensation in two fingers, she promptly lost sensation over the whole hand, when advised to wear protective bandage she banged her hand and "took a chunk out of it"

The attitude of these patients to the affected limb differs from that of the organically ill they carry the arm as if it did not belong to them or were not part of them, much as patients with non-organic palsy of the leg drag it without attempting circumduction Mentally they are equally indifferent, they are unconcerned about loss of function and apparently resigned to their condition Indeed both patients clamoured for amputation the first said "I hate this ugly thing", the second insisted that amputation was "the best solution" During examination the patient does not anxiously watch the limb, like patients with organic disease, but looks at the examiner with an expression as of a point scored Paralysis tends to be more complete, anæsthesia more uniform, pain more constant, swelling more widespread, than in organic lesions The condition may remain stationary for years—which, as Babinski pointed out, is unknown in organic affections

Management

Once the condition is recognised as of psychological origin, no attempt should be made to apply physical treatments, which are always taken by patients as confirmation of their belief that their complaint is physical and not mental, making them more refractory to psychotherapy Wilks (1883)

> "could not speak too strongly in denunciation of the old fashion, the plan of treating hysteria by physic instead of moral means which was known to be useless, and yet was followed as a matter of routine It cannot be presented too strongly that the mere absence of treatment by physic is a positive stage towards the cure"

In each of the present cases the patient's condition was aggravated by physiotherapy, immobilisation almost beats the patient at his own game and "always has disastrous results" (Charcot 1890) Local treatment of any kind converts a symptom into a self-perpetuating disease, by preventing "the attention being abstracted from the local symptom" (Brodie 1837) Indeed it is best for patient and doctor not to concentrate on the local complaint.

> "To 'make an effort' is sheerly detestable to the hysterical patient, and as impossible but to exert herself, almost unconsciously, because a motive is supplied, is scarcely felt to be an effort" (Reynolds 1872)

The physician must show "painstaking appreciation of the patient's own feelings, determinate assurance that the disease is no idle fancy" (Reynolds 1872), "It is very erroneous, when patients are charged with imagining or inventing their sufferings" (Paget 1873). It is the essence of the illness that patients cannot see that their symptoms arise from an unconscious idea or emotion (Macalpine 1954), they behave much like patients with frank delusions, who are not amenable to rational argument, objective evidence, or reassurance.

We cannot here discuss details of psychotherapy; we conduct expectant, non-interfering, *face-to-face* interviews Interestingly Charcot himself warned that in these cases "the abuse of hypnotism has been followed by very serious complications" (Charcot and Pierre Marie 1892)

Psychological Significance

"It is not that the muscles are incapable of obeying the act of volition, but that the function of volition is not exercised" (Brodie 1837). "She says, as all such patients do, 'I cannot', it looks like 'I will not' but it is 'I cannot will'" (Paget 1873) Yet there is no lack of will-power in other spheres (It is historically interesting that Paget (1873) suggested "It may be due to mental association, perhaps unconsciously").

Loss of movement and sensation express the idea that the limb is to the patients' "[illegible]" (Greatraks 1666) Hence they avidly accept anything which seemingly confirms this belief This phenomenon misled Charcot into postulating suggestibility as the hallmark of hysteria But patients need not be generally suggestible, they are so within the confines of their morbid ideas

It is the function of psychotherapy to trace out the development of patients' feelings and ideas Case 1 spoke of her arm and her family in identical terms she wanted to cut herself off When the unbearable confusion of love and hate to mother and foster-mother was worked through, the condition cleared up Case 2 was from early childhood deeply affected by sympathy for her invalid father, and concretely expressed this by "suffering with" him—psychologically speaking, she identified with him A striking feature in both was the concreteness of expression achieved in the symptoms, which is characteristic

Psychiatric Significance

These patients illustrate the transition from somatic symptoms arising in the mind to mental illness proper (Macalpine 1954) Concrete thinking as opposed to conceptual, abstract thinking is common in mental disorders The same is true of serious persistent disregard of one's own interest, which our patients displayed by readily accepting their disability, indeed their insistence on amputation may be regarded as a degree of self-mutilation amounting to partial suicide Their inaccessibility to objective evidence and reassurance differs from frank delusions only by their false beliefs being centred on *their body and not on the outside world.* Thus cases of *oedeme bleu* illustrate the early or mild stages of mental *illness*, the disorder still being confined to the patient's relation to himself, to his mind and his body (Macalpine and Hunter 1955) The presenting symptom must not be regarded as a foreign body to be removed; rather it plays a vital part in the mental economy, and if treated in isolation or by physical means patients may be much worse off Other somatic symptoms equally likely to be misunderstood and hence mismanaged may appear, or a frank psychosis may develop This is confirmed by patients in whom the condition alternates with periods of psychosis (Brodie 1837)

Recognition of localised abnormalities such as *oedème bleu* is therefore of immediate practical importance, and their study may advance our understanding of mental illness in general.

Summary

Two cases of *oedème bleu* are reported, and the condition is discussed in its historical, clinical, psychological, and psychiatric aspects.

We thank Mr. N. K. Harrison, of the photographic department, for the figures.

A CASE of postpartum hæmorrhage associated with a deficiency of fibrinogen was reported by Kelsey and Muirhead (1955), who found that few such cases had been published We describe here a further case, in which severe hæmorrhage occurred during a lower segment cæsarean section done for prolapse of the cord

Case-report

A woman, aged 38, who had previously borne three children, was admitted as an emergency case to the Gables Maternity Hospital, Peterborough, in labour with a prolapsed cord, at 3 30 A M on Sept 29, 1955 Lower segment cæsarean section was performed at 4 A M The placenta was found attached to the lower segment (anterior wall of the uterus) as a type-1 placenta prævia, the amniotic cavity was incised lateral to the placenta, which was displaced medially A healthy female infant weighing 7 lb 15 oz was delivered Hæmostasis was difficult to achieve, 55 oz of blood being lost during the suturing of the uterine incision A specimen of blood was taken from an arm vein for grouping and cross matching, and an intravenous drip was set up 'Intradex' 2 pints was given, followed by one bottle of 4 3% dextrose and 0 18% saline solution

6 15 a m blood pressure (B P) 80/60 mm Hg, pulse rate 110

7 a m B P 80/60 A few minutes later a report was received from the consultant pathologist that the specimen of venous blood taken during the operation, before the start of intravenous therapy, had not clotted

8 15 a m triple strength plasma (small pool) was given intravenously with 'Synkavit' 50 mg

8 30 a m B P 80 75

9 30 a m B P 116 76

10 15 a m B P 105/75 pulse rate 100

11 15 a m clinical improvement, less bleeding per vaginam and blood beginning to clot

12 45 p m fibrinogen 186 mg given into intravenous drip

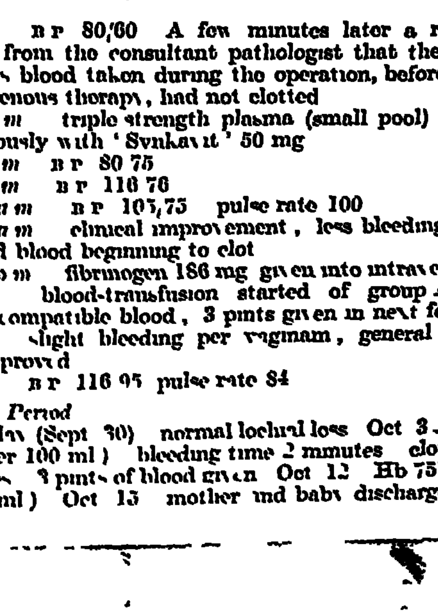
1 p m blood-transfusion started of group A rhesus-positive compatible blood, 3 pints given in next few hours

4 p m slight bleeding per vaginam, general condition much improved

7 p m B P 116 95 pulse rate 84

Recovery Period

Next day (Sept 30) normal lochial loss Oct 3 Hb 58% (8 2 g per 100 ml) bleeding time 2 minutes clotting time 4 minutes 3 pints of blood given Oct 12 Hb 75% (11 0 g per 100 ml) Oct 15 mother and baby discharged well



Paper electrophoresis of plasma a first specimen, not showing any fibrinogen b second specimen showing fibrinogen (level was 312–313 mg per 100 ml).

Electrophoresis

The first specimen of venous blood still failed to clot after 102 hours A second specimen of venous blood was taken at 2 P M on Sept 29, and both specimens were examined in the Department of Medicine, Cambridge University Medical School The results of paper electrophoresis of the plasma are shown in the accompanying figure No clot was obtained with the plasma taken before the administration of any intravenous therapy The plasma taken 75 minutes after fibrinogen had been given contained 312–313 mg of fibrinogen per 100 ml of plasma

Discussion

If the blood ceases to clot, replacement of fibrinogen is urgently needed This can be done either by giving fibrinogen intravenously (fibrinogen can be obtained from regional blood-transfusion centres but is in short supply) or by infusion of plasma of double, treble, or quadruple strength (Barry et al 1955), made up by simply adding respectively a half, a third, or a quarter the usual volume of water This should be sufficient, in most cases, to correct afibrinogenæmia (Scott 1955)

Intradex or a similar preparation should be given to help to restore the blood volume, pending the arrival of fibrinogen from the regional blood-transfusion centre This should be done in spite of the considerable clinical and experimental evidence that dextran can impair the coagulation mechanism In view of this evidence, however, it seems wise to limit the use of dextran to 1 or 2 pints, and to follow this up as soon as possible with transfusion of grouped cross matched whole blood

Small test-tubes should be kept ready in obstetric units to enable the clot observation test to be carried out Weiner et al (1953) say that, even when clotting takes place, it may be followed within an hour by fragmentation and dissolution, and that, if this happens fibrinogen should be given immediately to restore the ability of the blood to clot Multiple whole blood transfusions will not do this

The patient showed clinical improvement at 11 15 A M after the administration of triple strength plasma by intravenous infusion, the clot formed being soft and mushy The fibrinogen (186 mg) was given at 12 45 P M —i e, 4½ hours after the plasma The normal range of plasma-fibrinogen level is about 220–400 mg per 100 ml and in pregnant women near term about 450 mg per 100 ml (range 300–600 mg per 100 ml during labour) We therefore consider that the infusion of triple strength plasma restored the clotting-power to almost normal and that the small dose (186 mg) of fibrinogen restored it to normal

Barry et al (1955) state that when rapid coagulation is essential, pure human fibrinogen 4000–6000 mg should be given intravenously

Summary

A case of afibrinogenæmia associated with massive postpartum hæmorrhage after a lower-segment cæsarean section is described

It was treated by intravenous infusion of fluids and of plasma blood transfusion, and intravenous injection of fibrinogen

We should like to express our thanks to Miss L M Gales matron of the hospital, and her staff, to Dr F E [illegible] consultant anæsthetist to Dr D H [illegible] senior consultant pathologist, to Dr C V B W[illegible] of the regional blood-transfusion centre, Cambridge and to Dr J F M[illegible]ard and Dr M J Ne[illegible] of the department of medicine Cambridge University Medical School

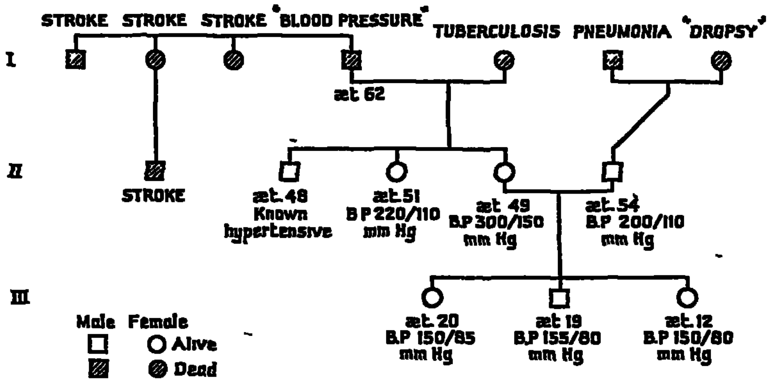
A HYPERTENSIVE FAMILY

L E WEAR
M B Leeds, D C H
GENERAL PRACTITIONER

IN 1947 Platt stated that he had not yet discovered a family in which all the siblings had essential hypertension and that neither had Weitz Both these workers, however, found a strong suggestion of heredity in essential hypertension in about 75% of cases (Platt 1947, Weitz 1923)

I report here a family with three generations of hypertensive patients (see figure) All the first generation died of stroke except one who died of "high blood-pressure" at the age of 62

All three of the second generation are alive, although somewhat precariously, and all have hypertension I have personally examined two, and I am told that the brother who lives away is having treatment for "blood-pressure" One of the sisters is married to a man with a moderate hypertension (200/110 mm Hg), and they have three children aged 20, 19, and 12 years (third generation) All these three have a systolic blood-pressure on the high side, particularly the girl aged 12 years All the readings were taken with the patients at home resting in an armchair and were repeated several times Urinary albumin was absent in all the third generation and in their mother The others were not tested



A hypertensive family

In the second generation two daughters and a son, all living have hypertension, and a cousin of theirs died of a stroke

Discussion

The normal blood-pressure of children aged 12 years is 102–115 mm Hg systolic and 62–72 mm Hg diastolic (Holt and McIntosh 1940), the blood-pressure of the girl aged 12 years is abnormally high at 150/80 mm Hg The elder girl, aged 20, has a blood-pressure of 150/85 mm Hg and the boy, aged 19, one of 155–80 mm Hg These are the lowest recordings and can be considered higher than normal for children of their ages

On their mother's side of the family there seems to be a dominant gene which has become apparent in all near blood-relations Their father also has moderate hypertension Unfortunately his brothers and sisters cannot be traced All the three children are well

I intend to follow up the third generation as far as possible, but marriage has taken away the eldest girl and the Services the boy, scattering the family, and family reunions are hardly the time for the doctor to appear, armed with his sphygmomanometer, like a spectre at the feast

It is generally agreed that death from apoplexy, be it cerebral thrombosis or cerebral hæmorrhage, is associated with hypertension (Brummer 1947) Thus all the first generation must have been hypertensives

Summary

Three generations in a family have been hypertensive, all those living have hypertension and those deceased had hypertensive deaths

In the third generation, slight but persistent hypertension is noted in a girl aged 12 years, a boy aged 19, and a girl aged 20

ACUTE CHYLOUS PERITONITIS

J C WALKER
M C, M B Glasg, F R C S E
ASSISTANT SURGEON, GREENOCK ROYAL INFIRMARY

THE presence of chyle and chylous fluid in the abdominal cavity is unusual, and it is particularly rare to find acute peritonitis in association with a chylous ascites I could find no reports of acute chylous peritonitis in British literature, but 27 cases have been described in American and European journals Hoffman (1954) collected 23 cases, and added 1 of his own, Jackson (1953), Olechowski and Froyd (1952), and Kelemen (1954) each described single cases Every case was regarded as an "acute abdomen," and the diagnosis was established at laparotomy

Case-report

A forester aged 27 was admitted to hospital complaining of severe abdominal pain of eight hours' duration The pain, which began soon after he had eaten a breakfast of bacon and eggs, was felt first in the costovertebral angles Later, it travelled round to the umbilical region, and then to the right iliac fossa where it persisted The pain was constant and intense, with occasional exacerbations Nausea was continuous, and the patient vomited once before admission Micturition was normal, and he had had a recent bowel movement, and passed flatus

He had been in another hospital eighteen months previously with "appendicitis," but he was discharged without operation Seven years ago, some tuberculous glands of the right side of the neck were excised

When first seen in hospital, the patient was rolling about in bed and crying out His face was flushed, sweating, and anxious His blood-pressure was 120/78 mm Hg, temperature 97°F, pulse 98, and respirations 34 per min His abdomen was rigid on the right side and there was guarding on the left side There was no abdominal movement on respiration He was tender all over the right side, especially in the right iliac fossa Bowel sounds were diminished Liver dullness was within normal limits There was considerable tenderness on the right side on rectal examination Analysis of his urine was normal White count was 8500 per c mm Straight X-ray examination of the abdomen was normal.

No definite diagnosis was made, but laparotomy was considered essential to exclude acute pancreatitis or perforated duodenal ulcer, with tracking of bowel contents down the right paracolic gutter

Operation —As soon as the peritoneum was opened, the wound was flooded with chyle, of which about 12 oz was aspirated.

The cæcum was completely white, and the ascending colon patchily so, as if milk had been injected under the serous coat The mesentery of the ileum, the mesocolon, the pancreas, and several small areas on the posterior abdominal wall were similarly affected Free chyle lay in Morison's pouch, the right paracolic gutter, and in the rectovesical space A mass was felt behind the stomach, so the wound was enlarged upwards.

There was an irregular, craggy mass, measuring about 3×2×1 cm, on the posterior abdominal wall of the lesser sac, over the 2nd and 3rd lumbar vertebræ, and from the middle of it came a trickle of chyle No other abnormality was found The mass was friable and looked tuberculous, but a neoplasm could not be excluded A small piece was excised for histological examination

Closure of the leakage was difficult, but the opening was patched with a piece of omentum, a large "cigarette" drain was inserted into the lesser sac through the gastrocolic omentum, and the wound closed round it

Pathological Report—"The tissue submitted is a small lymph-node Microscopy shows numerous foci of caseation with surrounding epithelioid cell reaction, and occasional giant cells The appearances are those of tuberculous lymphadenitis The fluid is milky in appearance, alkaline in reaction, and its specific gravity is 1014 There is no change in the fluid on standing, and it is sterile on culture both on ordinary and Löwenstein Jensen media Microscopy shows numerous finely divided fat particles approximately 2 µ in diameter Only occasional lymphocytes are seen in stained smears The appearances are consistent with a chylous effusion"

Subsequent Progress—The patient's pain was abolished as soon as drainage was instituted, and his convalescence was uneventful until the eighth postoperative day, when a small-bowel obstruction developed, and a further operation was carried out Several loops of ileum were found to be adherent, but the loop responsible for the obstruction was easily freed All the subserosal collections of chyle had disappeared Following this, his progress was uninterrupted, and he was discharged on the twenty-fourth postoperative day He was quite well two years after the operation

Discussion

The physiology and pathology of the lacteal system are imperfectly understood, and one can only speculate on the reasons underlying the findings in this case The free fluid in the abdomen was, in the main, pure chyle and not a transudate, as chyle was seen trickling from the mass overlying the cisterna chyli Subserosal collections of chyle were widespread and patchy in distribution, and it is unlikely, therefore, that these were caused by retroperitoneal spread from the tuberculous mass overlying the cisterna chyli It is more likely that the inflammatory mass caused obstruction, not only to the main lymph but also to the collateral channels Lee (1942) showed experimentally that ligature or section of the main thoracic duct alone did not produce chyloperitoneum, because a collateral circulation was rapidly established

Presumably, when the main lumbar channels and the collaterals were obstructed in this patient, back pressure was built up and some of the peripheral lacteals ruptured, allowing chyle to spread in the subserosal layer Subsequently a leak must have occurred in the soft tuberculous mass, and acted as a safety-valve Collateral channels must, however, have opened up after the first operation, because there was no sign of subserous collection of chyle eight days later

The initial lumbar pains were possibly caused by increasing pressure in the main lymphatic trunks and distension in the subserosal layers, the change of site to the right side of the abdomen being due to irritation of the peritoneal cavity by free chyle

Peritoneal reaction following the first operation was sufficient to cause multiple adhesions and obstruction, but the origin of this and of the pain is obscure, because free chyle usually produces little or no pain or reaction in the abdomen or thorax Blockage of the main lymph-ducts by microfilaria causes stasis, distension, and final rupture of the distended lacteals, but no pain, however, this is a gradual process and is not exactly comparable, as it produces transudates also

Possibly chyle, in concentrated form, contains some irritant factor, but Wells (1920) found little to suggest its identity, unless it is a diastatic enzyme

In only 8 of the 27 previously described cases were any lesions found at operation, and in only 3 of those was the lymphatic system affected (Guldmann 1921, Dutton 1930, Jackson 1953)

The prognosis is good in most of the acute case
less satisfactory in chronic cases Only 3 fatal ca
acute chylous peritonitis have been recorded
associated lesions were paralytic ileus (Papenberg
lymphosarcoma (Jackson 1953), and miliary tu
losis (Reboiras and Giralt 1938)

Abnormalities in the abdomen may be correct
operation, but closing the ruptured chylous duct is
difficult The patch technique worked in this patien
the establishment of a collateral circulation was
With regard to wound drainage, 18 of the pa
previously described were drained and 9 were not,
was no appreciable difference in the convalescence
2 groups

Summary

Acute chylous peritonitis was diagnosed at laparot
The predominant feature was a tuberculous obstru
and erosion of the lumbar lymphatic trunks
erosion was closed with a patch of omentum, and rec
was rapid

Preliminary Communication

THE EFFECT OF PARA-AMINOSALICYL ACID ON HYPERTHYROIDISM

SINCE the first report by Clausen and Kjerulf-Jen
many investigators have reported that in some pat
the prolonged administration of *p*-aminosalicylic
(P A S) is followed by the development of goitre
or without myxœdema Recent investigation by B
et al[2] and Macgregor and Somner[3] has appare
shown the anti thyroid activity of P A S We re
here the effect of P A S on hyperthyroidism,

Calcium P A S *15 g a day by mouth was given*
3 male and 10 female hyperthyroid patients

Level of protein bound iodine in patients with either slight or moder
hyperthyroidism, showing decrease to normal range under tre
ment with P.A.S

RESULTS OF TREATMENT OF HYPERTHYROIDISM WITH P A S

Result	Administered longer than 2 mos	Discontinued within 2 mos because of pyrexia	No of cases
Full control	5	1	6
Control→relapse	2	1	3
No improvement	3	1	4
Total	10	3	13

The patients with either slight or moderate hyperthyroidism were improved by P A S The accompanying figure shows that the amount of protein-bound iodine in the serum of these patients decreased to the normal range under the treatment The basal metabolic rate of the patients in whom this happened fell significantly

In 4 patients with severe hyperthyroidism the amount of protein bound iodine in the serum either decreased temporarily or did not decrease at all under the treatment 3 patients with moderate hyperthyroidism in whom the amount of protein-bound iodine in the serum decreased to the normal range relapsed under the treatment (see accompanying table) The 24-hour uptake of ^{131}I by the thyroid glands of the patients who responded to treatment was considerably diminished, but that of the patients who did not improve remained unaltered by the treatment with P A S

3 patients developed pyrexia, during the treatment, this was intermittent and fluctuated between 98°F and 102°F As soon as the P A S was discontinued, the pyrexia disappeared The relation between the severity of the hyperthyroidism and toxicity is indicated in the table, which shows that P A S is apt to be toxic to patients with hyperthyroidism

P A S is an aromatic anti thyroid substance which inhibits the binding of tyrosine and elemental iodine[4] Its anti-thyroid activity may be compared with that of *p* aminobenzoic acid, with which Berman[5] and Goodwin et al[6] successfully treated hyperthyroidism Though the anti-thyroid activity of P A S in euthyroid people is weak according to our experience about half our patients with hyperthyroidism responded to P A S We cannot recommend P A S for all patients with hyperthyroidism, but it may be useful in the treatment of tuberculous patients with hyperthyroidism

New Inventions

JEJUNAL-BIOPSY TUBE

JEJUNAL biopsies can be obtained by a modification of the duodenal-biopsy tube described by Shiner[1] Fig 1 shows the component parts of the biopsy tube, and fig 2 a sample biopsy

The tube, which is flexible, measures 161 5 cm in length and 5 mm in diameter The headpiece is 2 5 cm long and has a diameter of 1 3 cm at its widest point The diameter of the biopsy hole is 3 5 mm The knife-cylinder is 9 mm long and is ridged at its distal end An air-hole is situated in one of its ridges extending down the side of the knife-cylinder, thus allowing air to reach the rubber balloon at the distal end of the headpiece. The tailpiece of the tube is essentially the same as that in the duodenal-biopsy tube except that it is longer and allows more play in the movement of the wire, which has to travel a greater length within the flexible tube

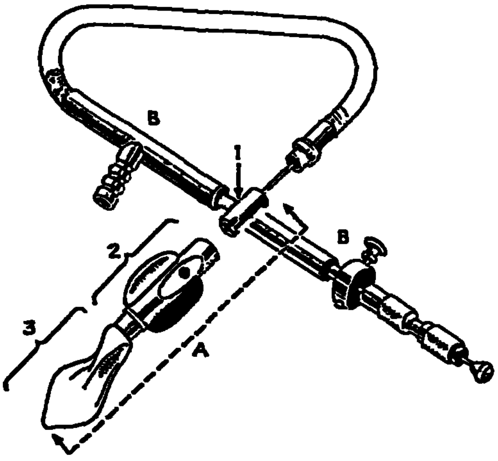

Fig 1—Jejunal-biopsy tube A headpiece (1) knife-cylinder, (2) biopsy head (3) balloon B, tailpiece with lateral exhaust.

The tube is introduced in the same way as the duodenal-biopsy tube and its course is guided fluoroscopically When the first part of the duodenum is reached the balloon is inflated and guides the headpiece along into the jejunum The balloon is an essential part of the jejunal-biopsy tube as it has been found impossible to make the headpiece travel through the third and fourth parts of the duodenum without it

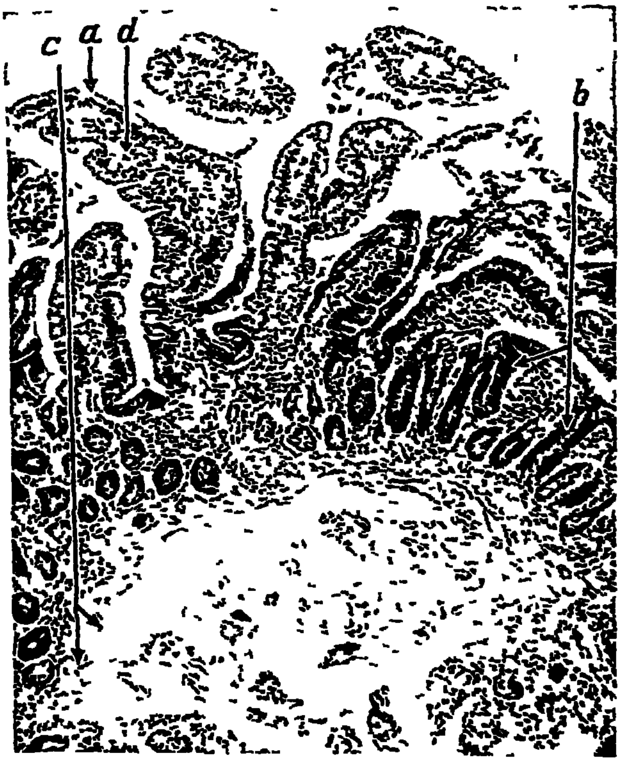

Fig 2—Jejunal biopsy (a) villi (b) crypts of Lieberkühn, (c) muscularis mucosæ (d) cellular infiltration (× 80)

Fig 2, from a specimen taken with the jejunal-biopsy tube, shows the full thickness of the jejunal mucosa with well-preserved villi, and the muscularis mucosæ

I should like to thank Mr G Hawkins, of the Genito-Urinary Manufacturing Company, for his invaluable help in the construction of the instrument

Reviews of Books

Munk's Roll

Vol IV Lives of the Fellows of the Royal College of Physicians of London, 1826–1925 Compiled by G H BROWN, M A, B LITT London Royal College of Physicians 1955 Pp 637 *42s*

William Munk's *Roll of the Royal College of Physicians of London* was first published in 1861 Its two volumes contain biographical sketches of the 1351 fellows and licentiates admitted to the college from its foundation in 1518 to the end of the 18th century A third volume published in 1878 added 372 lives to the total, and carried the record forward to 1825, the year of the college's removal from Warwick Lane to its present site in Pall Mall East The fourth volume, which was largely inspired and launched by Sir Henry Bashford, extends the *Roll* (of fellows only) over a further century It contains short biographies of the 874 fellows who were elected between 1826 and 1925 and who died before Jan 1, 1954 They have been written to a certain standard of detail and a rough (not a rigid) uniformity of presentation, the aim being to ensure that the same detail, when available, is provided in each biography, rather than that they should follow the same exact pattern. No attempt has been made to include complete bibliographies of fellows' writings, but their more important works are named in the text, and there is usually some indication of the branches of medicine in which they were particularly interested

These biographies cover a century of unprecedented change in the practice and organisation of medicine in the British Isles, and in every development fellows of the college played a significant part Marshall Hall, William Gull, William Jenner, Samuel Wilks, Andrew Clark, John Hughlings Jackson, Clifford Allbutt, William Osler, Patrick Manson, Bertrand Dawson, David Bruce, Charles Sherrington, and Frederick Gowland Hopkins were among them Their influence and interests were not confined to medicine, and these biographies relate, too, something of their many activities in other spheres of life The aim has been to convey in small bulk a picture of the man

The four volumes of *Munk's Roll* are a most useful source of information not only about the college in the four centuries of its existence but about the practice of British medicine generally during the same period

An Atlas of Regional Dermatology

G H PERCIVAL, M D, PH D, F R C P E, professor of dermatology, University of Edinburgh, T C DODDS, F I M L T, F I B P Edinburgh E & S Livingstone 1955 Pp 264 *£5*

To produce a book containing 475 colour photographs at a net cost of about 2½*d* per picture is in itself something of an achievement On the whole the colours are adequate and comparable The choice of material is largely representative of the commoner diseases the authors set out to illustrate, but "lupus erythematosus profunda" is a strange choice for two pictures in an elementary text Two other illustrations appear to be colour prints of photographic transparencies of drawings of moulages of patients and it is not surprising that the final effect is unlifelike

The size of the pictures does not permit the demonstration of the finer details of morphology upon which dermatological diagnosis must at times depend, but this book should help those students and practitioners who discover too late that the place to learn dermatology is in the outpatient department of a busy hospital

Die Tests in der klinischen Psychologie

Zweites Halband Editor *Prof Dr* ERICH STERN Zurich Rascher 1955 Pp 450 Sw fr 31 50

IN this volume a number of tests are described which have been used in France, Germany, and Switzerland but are little known in the English-speaking countries

Thus the colour test devised by Max Luscher, of Basle, the pyramid test which Robert Heiss developed on the basis of a method used by Max Pfister, the Wartegg test (here expounded, not very plainly, by its author), and the Sceno test developed by Gerdhild von Staabs are reported in sufficient detail to enable the reader to judge whether he wants to inquire more closely into their theory and clinical or experimental use In most instances he may well conclude that ingenious and potentially useful though they are, the humdrum processes of standardisation and validation should have been applied to them before they were put out as clinically valuable The chapters dealing with familiar tests, such as the Rorschach, do not bespeak an effort at critical appraisal, but rather the attachment which people have to loyal servants and long used tools

Neuroglia

Morphology and Function PAUL GLEES, D PHIL, M D, demonstrator and lecturer in physiology, University of Oxford Oxford *Blackwell Scientific Publications* 1955 Pp 111 *25s*

MUCH of the classical work on the morphology of the glia has been written in German and Spanish This review is therefore useful in that the widely scattered literature has been brought together in concise form The subject is treated historically the anatomy and physiology of the astrocyte, the oligodendrocyte, and the cerebral histiocyte are discussed in turn, and Dr Glees gives his own views which are founded on his morphological studies, largely with silver techniques He justly pays tribute to the important work, so often overlooked, of Ford Robertson in this country At the end of the book there is a short account of the contributions made by the few workers who have so far made use of tissue culture, and the hope is expressed that before long more precise knowledge of the metabolic function of these cells will materialise with the aid of this essential technique

As the concept of glial structure and function is by no means easy, the subject calls for rather more emphasis on the living rather than the fixed cell, but in the present imperfect state of physiological knowledge this is no easy task for an author

Ionography

Electrophoresis in Stabilised Media HUGH J MCDONALD, D SC, professor of biochemistry, Stritch School of Medicine of Loyola University, Chicago Chicago Year Book Publishers *London Interscience Publishers* 1955 Pp 268 *48s*

ELECTROPHORESIS, and particularly paper-strip electrophoresis, is being used increasingly in clinical chemistry, although there are some who believe that it is a technique better kept for the research laboratory This useful book is a comprehensive survey of the vast literature devoted to the technique of electrophoresis on paper and in starch columns and other stabilised media

There is an historical introduction, and a chapter on types of apparatus with an admirably objective viewpoint Methods of scanning are described and criticised, and there is a long section on the determination of electrophoretic mobilities using paper strips The last five chapters deal excellently with the application of electrophoresis in medicine, biochemistry, and chemistry

Arctic Doctor

Dr JOSEPH P MOODY, with W DE GROOT VAN EMBDEN London Odhams Press 1955 Pp 256 *15s*

THE subtitle—an account of strange adventures among the Eskimoes—hardly does full justice to the merits of this book, for Dr Moody has managed to tell in relatively few pages a thrilling tale of his life and work in the Canadian East Arctic The adversities of the climate and the handicaps of single-handed work in this outpost, with a population scattered over 600,000 square miles, necessitated travelling by dog-sledge, canoe, and small aircraft, and sleeping in igloos It entailed the risks of treatment by radio telephone when travelling was impossible, and the control of an epidemic of poliomyelitis To face this task, Dr Moody was well equipped with a mind receptive to the beauty of wild life and Nature (there is a fine description of the aurora borealis), and he was fortified by a strong sense of humour which helped him in his approach to the Eskimoes and the study of their lore, and eventually rewarded him with their confidence

THE LANCET
LONDON SATURDAY, JAN 14, 1956

Food-poisoning

When illness is caused by staphylococcal enterotoxin, symptoms appear so rapidly that the sufferer may make a reasonable guess at their origin and the investigator may be able to save some of the suspected food for examination Salmonella infections, on the other hand, have an incubation period of up to forty-eight hours, and by this time memories are dim and the dustman has called Nevertheless, medical officers of health and bacteriologists must admit that 39% is too large a proportion of all "incidents" to be written off as "cause unknown" this is the figure given in the report[1] of the Public Health Laboratory Service on food-poisoning in England and Wales in 1954—a report which, like its forerunners, is a clear and objective study that makes the best use of information much of which is for many reasons incomplete Clostridial food-poisoning won its first mention in the report for 1951–52, and it may be that imagination and careful bacteriology will reveal other bacterial causes in due time As in many other diseases of doubtful origin, an unrecognised virus has been suggested as a cause of some outbreaks of food-poisoning In the absence of much evidence it would be wise to take a firm grip of Occam's razor Perhaps the chemical examination of food is pursued upon a too-stereotyped plan there are other irritants than the heavy metals, and few doctors or chemists know all the secrets of food-processing But probably the lack of any animals (other than the long-suffering laboratory staff) which may be used to detect bacterial terotoxins is the greatest handicap to increasing knowledge of the origin of food-poisoning

As in previous years, salmonellæ were responsible for more than half the incidents whose cause was known in 1954 Staphylococci and clostridia made up no more than 2% and 1% respectively of the total But these figures are misleading in that a large number of incidents due to salmonellæ were isolated infections while the other genera were associated with outbreaks involving many people The origin of these single infections with salmonellæ remains a mystery The infectious dose of most strains for man is large[2], the organisms may not be evenly distributed through infected food, and symptomless "infections" are not uncommon among the other members of the family of one with overt disease Perhaps the natural history of salmonella infection is not so straightforward as we used to think it may be that sometimes "food-poisoning" is a misnomer Among the vehicles of infection, "made-up" meat maintained its evil reputation, being responsible for 170 out of 250 outbreaks of known cause Re-heated meat is the source *par excellence* of enterotoxic food-poisoning, but sausages, brawn, and meat pies have all had their victims Six outbreaks (of which five were staphylococcal) were traced to tinned meat It took eputable canners a long time to live down their clumsy eginnings in the trade and it is regrettable that food which should in theory be sterile should once again be open to suspicion

The provisions of the new Food Hygiene Regulations[3] are beneficial, and in spite of some objections by representatives of the trade, they do not make any outrageous demands upon caterers Nevertheless the Food and Drugs Amendment Act, 1954, as a whole is a pointed example of the difficulty of regulating the trivialities of daily life by the written word It creates new offences but offers little hope of greater rewards here or hereafter No one can imagine that to punish the malefactor who smokes a cigarette while he wraps a pound of cod in newspaper will make much difference to the figures in future annual reports on the incidence of food-poisoning This Act will do some good but is unlikely to alter those figures very much Vaccination succeeded because smallpox was a horrid disease of which every one had some experience The same to a lesser extent (and helped by brilliant publicity) was true of the campaign against diphtheria If food-poisoning were disfiguring or produced lasting disablement it would not be difficult to whip up some strong feeling on the subject among the public at large As it is, food-poisoning is of little account to most of us because it is far more dangerous to cross Oxford Street on foot than to sup off a hotted-up dish of delicious stew No-one seems to have persuaded the man in the street that he eats his black pudding or saveloy at his peril, and, in truth, he who tries will not have an easy job Legislation which runs too far ahead of public opinion seldom has its designed effect

Medical officers of health have devoted much energy to local campaigns to improve the cleanliness of food and the way in which it is sold and served Some catering firms have seconded these efforts with commendable zeal If the results have been disappointing they have at least served as a warning of this Act and its consequences Before he begins another campaign to the same purpose, the medical officer of health might give some thought to adding to our knowledge of the essential causes of food-poisoning Few have experience wide enough to make that alone the basis for policy and action, and it is only by pooling knowledge (as the Public Health Laboratory Service reports do) that our understanding will increase No outbreak of food-poisoning is too small to deserve full inquiry Not long ago Sir **William Savage**[4] once again advised his colleagues of the advantages of investigating public health problems in person and on the spot It may be convenient to employ sanitary inspectors and health visitors as investigators, but no-one except the medical officer of health has the training and knowledge needed to make the best use of the evidence at hand

The Reluctant Patient

The problem of patients who leave hospital in defiance of medical advice has never received so much attention in this country as it has elsewhere, especially in France and America In France the question has recently been given added emphasis by new legal measures put forward for the treatment of alcoholism, of which the increase is causing much concern, and in the United States, by all accounts, the irregular

discharge of tuberculous patients is widespread These difficulties in the *treatment of tuberculosis* are much rarer in this country, but it would be unwise to dismiss as insignificant the irregular departure of patients from our sanatoria, because these people are often *infectious* and *may* be psychotic, and they usually come from and return to the poorer strata of society SNELL[1] found that during the period 1938–51 the over-all irregular-discharge rate for an English sanatorium was 16%, but it had fallen to 5% by 1954 The late Dr LORENZ and his team[2] at the Veterans Administration Hospital at Madison, Wisconsin, have made an extensive and systematic inquiry into irregular discharges and they have classified the patients involved into three groups leaving against medical advice (A M A), absent without official leave (A W O L), and disciplinary discharge (D D)

What leads these patients to take a drastic step which many of them know may lead to permanent ill health and even early death, quite apart from endangering their family? CALDEN[3] devised the Madison sentence completion form, containing 80 items which could be grouped for analysis, to give the patient's reaction to the diagnosis, rest in bed, hospital routine, his family and friends, and many other facets of his life before and during his stay in hospital Using these records, LORENZ et al were able to compare the background and character of 100 irregularly discharged patients with a similar number who stayed and were discharged only when they had received maximum benefit from treatment Of the irregular discharges, 81 were A M A, 10 were A W O L, and 9 were D D Factors which were not statistically significant between the two groups were age, race, marital status, distance of hospital from home, and activity of the disease, but occupation was of importance, and of the 100 who left irregularly 12 had no known occupation and 38 were semi-skilled Fewer irregularly discharged patients had had surgical operations, but this might well be because they had more extensive disease which in itself might have precluded surgical treatment at the time of their discharge, although perhaps not ultimately The average period in hospital for these patients was 148 days, compared with 260 for those discharged normally 40% of irregular discharges took place within the first 3 months, and only 8% after 300 days BEACHAM,[4] studying the records from Baltimore City Hospitals where the irregular-discharge rate among tuberculous patients fell from 51% in 1946 to 20% in 1951, concluded that the rate would fall even further if particular attention was paid to the patients' difficulties before their admission to hospital Women were often worried about the welfare of their children, and men about money matters If these worries could be eased before or soon after admission, the fretful patient would accept his lot much more readily And TEDESCO[5] declared that the physician first making the diagnosis of tuberculosis had a big responsibility, especially in indicating how long treatment might take In this country patients are often more fortunately placed the benefits of National Insurance include special financial provision for the tuberculous, and as the majority of patients are sent to sanatoria through chest clinics or hospitals they have an opportunity to discuss their disabilities and worries with the almoners and, through them, with representatives of the National Assistance Board Health-visitors can also play an important part in calming the family disturbance, especially by taking an interest in the welfare of the children TOLLEN,[6] in considering that the chief reasons why the American patient leaves against advice, wrote of pressure from outside the hospital (usually personal, social, and economic) and influences acting within the hospital, such as the patient's failure to adapt himself to the new life and his dislike of the environment TOLLEN also referred to the ill effects sometimes produced by the attitude of the hospital staff, from porters to physicians, by too strict regulations, and often by the treatment itself SANDS et al[7] came to similar conclusions, and they suggested that isolation, if necessary enforcible by law, was the solution to irregular discharge NORTHROP et al[8] have tried such a scheme for some years They had a reasonably attractive sanatorium with sufficient beds, in not too isolated a spot and staffed by a competent and sympathetic staff, with all the ancillary services of occupational therapy, recreation, vocational guidance, and a medical social service But the irregular-discharge rate was 44% in 1950, and some way of improving matters was sought For difficult patients who were judged unlikely to stay, 27 beds were reserved in a locked ward After two weeks' detention, the patients were allowed in the regular ward, but at the least sign of insubordination they went back to the locked ward It is not surprising to learn that the fire services had to be called in to advise on the safety of the hospital after two attempts had been made to burn down the ward A less severe method, more likely to find favour in this country, was devised by LORENZ et al[9] They noted that many patients left hurriedly in a tantrum, so they devised a slowing-down technique, again involving a special ward with a special doctor The patient who had rashly decided to go was put here while his clothes and money were brought and final investigations were completed, all the people in hospital who might have had a favourable impression on him called to discuss his problems and to say goodbye In the first six months after this ward was open, 24 patients were admitted to it at least once and 16 were dissuaded from leaving as a result the irregular-discharge rate of the hospital fell from 36% to 15% LORENZ *et al* conclude that the ward had this rather unexpected effect because patients did not like to have to explain why they wanted to leave hospital

What happens to the patients who cannot be dissuaded from leaving? BREWSTER and FLETCHER[10] concluded from follow-up surveys that the mortality rate among irregularly discharged patients is two or three times greater than in more amenable patients ALLISON[11] made the interesting point that as many as 47% of those *irregularly* discharged received further hospital treatment, but only 13 7% of those who left normally had to be admitted again

As we have said, these matters are of much less concern to chest physicians in this country than in the United States SNELL believes one reason is that here, where hospital beds are at a premium, patients do not willingly give them up , and they often stay longer than American patients, so that new patients can see the ultimate rather than the less impressive intermediate results of chemotherapy and surgery Moreover, it may be that in this country we are prepared to place ourselves more confidently in the hands of the doctors on the assumption that they know best Recent correspondence in our columns indicates that there are in fact a number of patients with active disease, usually among the poorer classes, who discharge themselves , like their American counterparts they may stay in a sanatorium longer if they are readmitted, but they may never be readmitted or not until they have infected a lot of people A recent case [12] serves as a reminder that for those who refuse to go to hospital, the law can be invoked and there are many people who say that it is not invoked often enough We have lately argued [13] that bold moves are now needed if the incomplete victory over tuberculosis is to be turned into a rout , and many chest physicians feel that one way of hastening the defeat of the disease would be to use sterner measures for controlling the intractable patient Among gentler means, the exchange of information about patients (chiefly financial and social) between sanatoria and chest clinics might be increased—for example, by weekly staff conferences at which potential irregular-discharge patients could be discussed Some sanatoria have earned bad reputations among patients, and an analysis of their irregular discharges might be illuminating and chastening The number of tuberculous patients who could thus be restrained from infecting their fellows would not be great , but now that the cooperative patient can almost always be made non-infectious quite quickly, the stubborn few have a new importance

Origin of Antibodies

THERE has been much speculation about the site of origin of antibodies and the mechanism of their formation , and the debate continues, though the field of the controversy is much narrower than it was, and it may even be possible to draw one or two conclusions without setting off the argument afresh No single organ in the body can be identified as the sole producer of antibodies On the other hand, antibodies are not produced at the local site of infection by the antigen, but they *are* formed in the lymph-glands draining the area The type of cell responsible for antibody synthesis is not known At one time lymphocytes were commonly believed to produce antibody, but emphasis has now shifted to the plasma-cell or its precursors Cytology, however, may have to advance a great deal further before we can be certain about the identification of many cellular elements and their life-histories Recently [14] the presence of antibodies in cells has been detected and localised by treating frozen tissue sections with the specific antigens, followed by antibodies which have been labelled by coupling with fluorescent dyes The distribution of antibodies after injection of antigen supports the view that the main site of antibody formation is the plasma-cells or their precursors , in comparison, the contribution of the lymphocytes is small For example, after intravenous injection of antigen into hyperimmune rabbits, little antibody was detected in lymphocytes, but much was found in colonies of plasma-cells present in the red pulp of the spleen, the medullary area of lymph-glands, the submucosa of the ileum, and the portal connective tissue of the liver For technical reasons the bone-marrow could not be studied After injection of antigen into the foot pads of rabbits, antibody was found in the popliteal lymph-glands Antibody was first seen in large immature cells in medullary areas of the glands As the cells differentiated and multiplied, colonies of typical plasma-cells developed and large amounts of antibody were detected in their cytoplasm Few antibody-containing cells were found after primary immunisation but many after a secondary stimulus when, of course, considerable quantities of antibody can be detected in the blood Primary immunisation may result in deposition of antigen in primitive cell types and the secondary antigenic stimulus produces the immediate synthesis of antibody and the development of mature plasma-cells containing the antibody It is suggested that the cell types responsible for antibody synthesis do not exist in the absence of antigenic stimulus The alternative view is that antibodies are formed in cells usually producing normal serum-globulin but the presence of an antigenically active molecular fragment has the effect of a "template" or mould According to this hypothesis, the globulin synthesised is similar to normal serum-proteins, but it is structurally related to the antigen and complementary to it It is now suggested that antibodies have no inactive normal prototypes The same technique has been applied to investigate the enhancement of antibody production by the addition of adjuvants, such as aluminium phosphate, to the antigen Antibody is formed first in the regional lymph-gland and later in the granulation tissue surrounding the nodule which develops at the site of inoculation The adjuvant effects are ascribed partly to delayed absorption of the antigen and prolongation of the antigenic stimulus in the lymph-gland and partly to the production of the local granuloma in which antibody-producing plasma-cells also develop The adjuvant effect of the wax obtained from tubercle bacilli is attributed to a widespread proliferation of plasma-cells in the lymph-glands, spleen, and liver and not to local stimulation of macrophage proliferation

Further light may be thrown on the mechanism of antibody synthesis by the transfer experiments that have been performed with splenic and lymphatic tissue

> Spleens were removed from rabbits which had had an injection of typhoid vaccine four days previously [15] The spleens, minced and suspended in a culture medium, were found to produce agglutinins for several days Antibody production was inhibited by respiratory and tissue poisons and also by cortisone The effect of cortisone may be to inhibit the proliferation of lymphocytes, plasma-cells, or other elements concerned in antibody

synthesis. Antibody-forming activity can be transferred from an injected rabbit into one that has not been immunised by transplanting cells teased from the lymph-glands draining the injected area.

It is now found[16] that if lymph-glands from normal unimmunised rabbits were treated with serum which had been in contact with *Shigella dysenteriae* and if suspensions of these glands were injected into irradiated rabbits, antibodies could be detected three or four days later. The transferred glands had not been exposed to antigenic stimulus in the donor animals but only in vitro, and the antigenic stimulus had not been in the form of bacillary cells but only soluble antigens passing into the serum with which the bacteria had been in contact. Furthermore the recipient animals had been irradiated to destroy their own powers of antibody formation. There is thus good evidence that the cells from the transferred lymph-glands were themselves the antibody-forming elements.

It is interesting to note that cells from mesenteric lymph-glands were effective in these experiments, whilst thymus-gland cells were not. On the other hand, intra-ocular transplants of thymus and Peyer's patch tissue conveyed antibody-forming activity.[17] The donor mice were immunised with tetanus toxoid, and fragments of tissue were transplanted into the anterior chambers of the eyes of mice which had been subjected to whole-body γ-radiation from cobalt-60. Significant but small amounts of tetanus antitoxin appeared in the blood of the recipient mice. When these mice received an intravenous injection of tetanus toxoid there was a specific anamnestic response and the serum-antitoxin rose considerably, although the irradiation had impaired the antigenic response of the recipients' own tissues. The transplants were effective in producing antitoxin in the donor mice only when the donors had been immunised by subcutaneous or intra-abdominal routes and not after intravenous immunisation.

Although the evidence is not conclusive, apparent in-vitro production of diphtheria and tetanus antitoxins has been reported[18] in fragments of lymph-glands and spleen excised from rabbits immunised with diphtheria and tetanus toxoids. The results of the in-vitro experiments seemed to run parallel with passive transfer experiments in which transplantation of lymphatic or splenic cells was followed by antitoxin production in the recipients. Again, passive transfer of cutaneous sensitivity to foreign serum-proteins has been produced by injecting washed leucocytes from the peritoneal exudates of rabbits exhibiting the Arthus phenomenon.[19]

More evidence about the rôle of leucocytes in the body's response to antigenic stimulus comes from work[20] on the fate of intravenous tuberculin in rabbits. Tuberculin protein which had been labelled by radioactive iodine was firmly adsorbed by leucocytes in the blood during the first few hours after injection. Although tuberculin was present in the plasma for some twenty-four hours after injection, no leucocytes containing tuberculin could be detected after the first four hours. Peripheral leucocytes may, therefore be responsible for transporting foreign proteins such as bacillary proteins or toxins to parts of the body remote from the site of their introduction. This would result in the accumulation of such substances in lymph-glands, spleen, and inflammatory foci where leucocytes congregate.

It is impossible to assess the full significance of all the complex results that are accumulating, but some points are clear. There are certainly good reasons for concluding that antibodies are produced in certain cells in lymph-glands, spleen, and elsewhere, and that these cells can continue to produce antibodies when removed from their original host and transplanted into another animal, or even when kept in culture outside the body. We still lack, however, a precise picture of the antibody-producing cells; we understand poorly the relation of antibody synthesis to the production of normal serum proteins; and we do not know how antibodies are produced which are specifically complementary to the antigens administered. The "template" hypothesis, which suggests that antibody is synthesised at the surface of the antigen molecule and thus has a configuration complementary to it, has been subjected to some criticism. This hypothesis requires that antibody be formed only as long as antigen persists in the antibody-forming tissues and cells. There has been no confirmation of in-vitro formation of antibody by the chemical treatment of a mixture of normal serum globulins and antigen. The alternative theory is that antibody synthesis is analogous to adaptive enzyme production. It is suggested that when once adapted to deal with a new type of antigen, cellular enzymes continue to produce antibodies by self-replication of their own structures until re-stimulated by a fresh dose of antigen. Experiments to decide between the two hypotheses of antibody formation have been carried out[21] with the T-agglutinin, an antibody present in normal serum which reacts with specially treated red cells. Treatment of mammalian red cells with cholera-vibrio filtrates removes a surface antigen, thus unmasking the T antigen. Animals immunised with treated red cells develop a high-titre T-agglutinin in the serum. The gradual modification of the T-agglutinin in immunised rabbits resembles the production of adaptive enzymes rather than a process dependent upon antigen "templates," and provides some evidence in favour of the adaptive enzyme hypothesis of antibody formation.

Annotations

POLIOMYELITIS ANTIBODIES IN CHILDREN

Before poliomyelitis vaccine becomes widely available in this country we must decide what is the best age for vaccinating children. And to do this we must know the commonest age at which children are infected in this country, so that they can be vaccinated before they are exposed to the greatest risks. But there is very little published information on the distribution of poliomyelitis antibodies in the sera of British children, and the paper by Dr. Fallon on p. 65 of this issue is therefore particularly welcome.

Dr. Fallon looked for antibody to all three types of virus in sera from 78 children living in Betws-y-Coed, in North Wales; this village was chosen because no case of poliomyelitis has been notified there since 1912, when the disease became notifiable. For comparison, he examined 71 similar sera from Liverpool where poliomyelitis appears each year. The sera were taken from infants and from children up to 14 years old, and the results of serological tests for poliomyelitis antibodies were recorded for different age-groups. The findings indicate clearly that in both Liverpool and Betws-y-Coed infection by poliomyelitis viruses in childhood is extremely common. In Betws-y-Coed, antibodies to type I viruses were found in the youngest children, and in the age-group 0–4 years 8 out of 22 children had antibody to more than one type of virus. The findings also suggest that infection by all three types of virus is quite widespread among Liverpool children, although there is a

possibility that infection took place later than in the Betws y Coed children Considerable variation in the age of infection can be expected in different parts of the country At a recent meeting of the Society for General Microbiology, Dr A P Goffe reported part of a similar investigation by workers at the Central Public Health Laboratory, Colindale They found that 70% of children under 5 years living in Southend had no poliomyelitis antibodies, whereas 80% of children from Belfast of the same age had antibody to all three types of virus Details of these and of similar investigations from different parts of the country are awaited with interest

Clinical infection in this country is, in general, less widespread than in the United States, but much more serious than it is, for example, in Egypt A comparison of serological findings in this country with those from certain areas in the United States and Egypt suggests that the extent of early infection in this country may also be intermediate between these two areas, but that there may be considerable variations between different parts of this country If we accept the recommendations of the recent World Health Organisation study-group on poliomyelitis vaccines, different areas of Britain may have to be treated differently in the matter of poliomyelitis vaccination for example, it would be hard to justify at the moment widespread vaccination in an area like Betws y Coed where subclinical infections seem to be immunising the population satisfactorily In other areas, the possibility of vaccinating children under 6 years will be raised, but the present evidence of the protection afforded by Salk vaccine extends only to children aged 6–10[1] Research on the protective effect of vaccine in younger children is an important future step

DISABILITIES OF OLD AGE

In many parts of the country the initial efforts of the newly formed geriatric units have been directed towards eliminating or reducing unnecessarily long waiting lists, to shortening the period of illness, to providing adequate treatment for the disabilities of old age, and to placing reabled elderly in suitable acommodation outside hospital Little has yet been done in the preventive medicine of old age, and major preventive advances are unlikely until more is known of the physiology of old age and of the natural history of the common disorders of the elderly Since ageing is a physiological process, it is essential for the clinician to distinguish between slight abnormalities of function due to physiological variation and the early manifestations of disease which will respond to early treatment

There have been few large scale clinical surveys of old people in localised communities, but Maddison et al[2] have recently published the results of a survey of 238 volunteers out of 550 people aged 60 or over who live in two Durham villages A thorough outpatient medical examination, including X-ray examination and laboratory tests, provided a mass of clinical data which was subjected to a factor analysis The determinables were sex, age, hæmoglobin, systolic blood-pressure, diastolic blood-pressure, and diseases found Since any old person may have four or even more diseases at any one time, this determinable can be subdivided into limitless attributes Maddison et al reduced the attributes to 42 by pooling some items with small frequencies, but they wisely point out that this arbitrary choice of attributes may mean that some of great importance are overlooked The factor analysis gave four groups which are thought to be closely related to blood-pressure Thus a systolic blood-pressure of 130 to 159 is associated with health and normal hæmoglobin, but a systolic pressure of 160 to 199 tends to be associated with low hæmoglobin and respiratory, heart and arterial diseases A diastolic pressure of 100 to 109 indicates a tendency to multiple disabilities and obesity whereas a diastolic pressure of 120 to 139 is said to reveal a tendency to malignant hypertension Few will be willing to accept a concept of malignant hypertension wholly based on sphygmomanometer readings made after a journey to an outpatient clinic, and many will doubt whether blood-pressure readings are sufficiently reliable to be used as determinables, except when repeated under basal conditions But the hazard of obesity and the part played by anæmia and malnutrition in predisposing to infection gain statistical significance from Maddison et al 's useful paper

ELECTRON-MICROSCOPY OF THE KIDNEY

The kidney was one of the first organs to be studied with the electron microscope, but reliable observation of its ultramicroscopic structure has been possible only recently, with the use of appropriate methods of fixation and thin section cutting The outstanding contributions have come from anatomists in the University of California and the Karolinska Institute in Stockholm

Pease[1 2] describes the fine structure of the three tissue layers separating the blood in the glomerular capillaries from the " urinary " space—namely, the endothelium, the capillary basement membrane, and the epithelium of Bowman's capsule As he shows clearly in beautiful electron-micrographs, the endothelium is not a continuous layer but has interruptions or pores 0 1 µ in diameter at a separation distance of 0 05 µ, thus forming a fenestrated membrane The capsular epithelium, which with the light microscope appears to be closely applied to the capillary wall, is also incomplete and like the endothelium does not form a continuous physical barrier These epithelial cells lie free in the urinary space They have thick cytoplasmic processes which give off finer branches interdigitating with those from neighbouring cells, and they are finally attached at regular intervals to the capillary basement membrane (on the other side from the endothelial cells) Bowman's capsule is therefore in the form of a cytoplasmic " lattice " with thick and thin cross bars and small channels 0 04 µ in width between the attachments of the thin processes to the capillary wall The basement membrane is a homogeneous layer 0 1 µ wide with a central layer and outer and inner cement layers related to endothelium and epithelium respectively Even with the highest resolution this layer remains a continuous structure with no evidence of a porous system, and thus it forms the sole physical barrier between the circulating blood and the urinary filtrate in the malpighian corpuscle The statement that the membrane is a " non-vital " barrier could however be challenged, because the term " vital " does not necessarily imply " cellular " There is a similar interrupted endothelial lining to the peritubular capillaries, with pores 0 05 µ in diameter—i e , about half the size of those in the glomerular capillary And a similar basement membrane separates the porous endothelium from the basal end of the epithelial cells lining the tubules

Rhodin[3] first described and illustrated the complicated system of double membranes which divides the basal part of the tubule cells into a number of cytoplasmic compartments open towards the apical end of the cell and containing characteristically large mitochondria correspondingly orientated Pease[4] interprets these double membranes as infoldings of the cell plasma membrane, and in his sections they are most noticeable in the

distal tubules and the thin segments where they may penetrate right through the cell cytoplasm, *forming* slots sealed off from the lumen of the tubules by cement bars It *is suggested that ionic interchange* between blood and urine occurs through these "slots" This complicated system of folds will increase the basal surface area of the cells *enormously and may be related to* the resorption of water At the apical end of the tubular cells the "brush" borders are finger-like extensions of cell cytoplasm—*short and stubby in the distal tubules* Here and there between the brush processes tiny canals penetrate into the cell substance often *opening into* vacuoles According to this analysis *of the fine structures* of the kidney, the "renal barrier" is in effect a system of pores, canals, and "slots"—a labile ultrafilter whose *varying pattern* will control the molecular interchange between blood and urine

Rhodin has attempted to follow by electron microscopy the cytological changes which accompany the resorption of albumin *He observed that* in the basal *cells of the proximal tubules there* was a fusion of mitochondria with loss of their internal structure as they combined with resorbed protein *to form very large* granules *These large granules eventually re-formed* into typical mitochondria These observations suggest that the *future story* of the pathology of the kidney will be an account of intracellular *changes*—and in *particular* how such changes affect the pattern of the tissue "filter" between blood and urine

HALLUX VALGUS

Harris and Beath[1] found *hallux* valgus in 2 2% of a group of young men, and there can be little doubt that the prevalence increases with age It is certainly more common in the lower social classes,[2] and *also in women* Many observers have noted its close association with an increase in the angle between the first and second metatarsals Truslow[3] suggested *that the primary defect* was one of adduction of the first metatarsal, but Hardy and Clapham[4] have shown that displacement of the metatarsal probably follows displacement of the digit

Studies of the feet of young children have thrown little light on the cause of hallux valgus There is a gradual deviation of the hallux to the outer side as age advances Craigmile[5] found the deviation to be greater in girls than boys at school leaving *age, but* Hardy and Clapham[4] found no such sex difference In normal adults there is apparently no sex difference in the position of the great *toe on radiographic measurement,*[6] but there is clearly a great preponderance of women amongst those who seek treatment for hallux valgus It is hard to reconcile such differing observations

It is commonly held that unshod races are not victims of hallux valgus Engle and Morton,[7] in a study of foot disorders in the natives of the Belgian Congo, do not mention it Wells,[8] however, noted a lateral displacement of *the hallux in the* South African Bantu, and other isolated examples have also been reported These unusual cases may be the result of various forms of arthritis[9] Barnicott and Hardy[10] have now examined the position of the *great* toe in West Africans In these people the hallux normally appears in footprints in line with the medial border of the foot, giving a mean hallux angle of zero In the footprints of the European male and female there is a *deviation to the outer* side of 6 9° and 11° respectively Some Africans, however, show a d*of more than 20° to the outer side* In general, the tion of the great toe of the African increases w and such a change *cannot be associated* with foot

Footwear undoubtedly plays a big part in pr symptoms, and may well increase the defo The importance of good shoes in controlling the of the great toe in children was well shown in the contributory shoe scheme,[5] in which adequate *and frequent shoe changes* were *followed by* a d in the deviation of the toe But, as we have som *said before,*[12] it will need some spectacular ch *fashion to* make people wear shoes that are g their feet, and naturally manufacturers are r to make shoes that are hard to sell

DRUNK IN CHARGE

WHENEVER a person charged with driving or " charge of" a motor vehicle while under the influ drink elects (as is his right) to be tried by jury, he nowadays a fairly good chance of acquittal have, on the whole, been reluctant *to bring in a* of guilty on *this* charge, largely because the o juryman is often not altogether satisfied by the p tion's evidence about the degree to which the was under the influence The alcohol content *blood is rightly recognised as only one point in estab* fitness or otherwise to be in charge *of a car* *tunately all the* other methods adopted by the (and by doctors summoned by the police) are unsystematic, and they may be unsystema applied, especially in parts of the country wh regular police surgeon's services are immediately able Greater uniformity at the first exami *(especially at the medical examination) of the accu* the police station, and greater uniformity in the test based on it, would do much to remove the impr of vagueness which the *jury properly interprets* in of the accused, even when there is no doubt doctor's mind that the driver was in a dan condition

It is therefore interesting to know that efforts for some years been *made by the medical profess* a number of Continental countries, particular Scandinavia, Western Germany, and Switzerlan *settle* in *outline certain guiding* points which invariably be considered by the doctor during examinations The Swiss journal, *Touring*, has pub the text of an unofficial questionary or aide me drawn up by doctors in cooperation with the polic the judiciary, which *has for some months been reg* handed to every doctor in the canton of Geneva as as he is asked to examine drivers suspected of drunk This aide *memoire* (which is filled in on the contains 12 main sections with a number of subs questions For instance, *the* examiner records d about the general aspect of the driver and any di ances of balance or coordination Writing and re tests are performed *After the first contact* has made, the patient is asked about his daily consum of alcohol and his health *Any additional* examin necessary are performed, and if there has been an acc any signs of cerebral damage are recorded If a sa of blood is taken, the exact *time is written down,* a note is made of any alcohol consumed between intervention of the police and the examination Fu *instead of first pronouncing* on the degree of drunken the doctor is advised to answer yes or no to the ques is this person under the influence of alcohol? "I does he appear to be slightly or seriously influen If he is under the influence of alcohol, have you no any fluctuation in his *ability to concentrate?* I you the impression that the patient is accustomed to alcohol or not ? "

This questionary contains no points which are wholly new, its value lies in the cumulative effect of the information assembled and in the anticipation of certain defences likely to be put forward Medical examinations conducted systematically and in close detail on this written basis can obviously give the courts far fuller and more uniform data about the state of the accused at the relevant time than they are now getting Although the document would not itself be admissible under the existing rules of evidence, there is no reason why the court should not allow the doctor in the witness box to refresh his memory by referring to his entries

BY-PASS OPERATION FOR ARTERIAL OCCLUSION

THE excision of diseased or damaged arteries and their restoration by suture or prosthesis is by no means a modern operation, and it can be traced back at least to the end of the nineteenth century, when Murphy, Payr, and Abbe experimented with suture techniques and glass tubes The principles of the eversion suture and endothelial approximation which often bear Carrel's name can be found in an article by Jaboulay and Briau published before the turn of the century In 1897, Murphy successfully excised an aneurysm and reconstructed the femoral artery by a circular invagination suture The widespread application of arterial repair and substitution had, however, to wait until operations could be confidently performed without fear of sepsis and until angiography was sufficiently developed to give the surgeon a clear idea of the problem facing him In the past decade much invention and energy have been directed to the re establishment of blood flow through the main arteries, and three important operations have been used —endarterectomy, excision and grafting, and finally the by-pass operation

Endarterectomy (the shelling out of the clot through a long incision in the arterial wall) has been followed too often by postoperative thrombosis extending proximally and distally, involving collateral vessels, and causing loss of a limb Excision of the thrombosed segment, with re establishment of continuity by means of an arterial graft or prosthesis, such as nylon, 'Orlon,' or 'Vinyon N,' is now a well-established and remarkably successful operation for large vessels such as the aorta and iliac arteries The mortality and morbidity after these operations were performed is surprisingly low, and although all the technical problems have not been entirely solved, the results are much better than those reported with other methods of treatment But the situation is quite different when smaller arteries, such as the femoral or popliteal, are excised and grafted Here the results are disappointing both in the immediate complication of limb gangrene and in the longer follow-up Crawford and De Bakey[1] have lately discussed why this is so They stress that the surgeon must know not only the extent of the occluded segment but also the state of the peripheral arterial bed well beyond the point of occlusion If the artery beyond is much narrowed and rigid, little benefit can be expected by the removal of the occlusion[2] It is even more important that any operation on a limb should be designed to minimise the interference to the collateral circulation The major collateral vessels, on whose preservation the viability of the limb depends, often arise in the patent lumen immediately proximal to the occlusion, and in such cases excision of the thrombosed vessel must include the valuable collateral supply Sometimes the diameter of the inserted graft is less than that of the destroyed collaterals, and if a secondary thrombosis ensues the limb of necessity becomes gangrenous

Crawford and De Bakey therefore use, for the treatment of arteriosclerotic occlusion of the leg arteries, the by-pass operation originally described by Kunlin et al[3] A graft is joined by end to-side anastomosis to the host artery above and below the diseased segment This operation is performed through two small separate incisions which are connected by a tunnel made with a probe or vein stripper As the incisions are well away from the vital branches, the collateral circulation is not in danger, and the host artery is undisturbed except through the two small incisions In fact, the operation simply adds an artificial collateral vessel about the size of the normal artery Crawford and De Bakey use for their anastomosis a freeze dried arterial homograft, the ends of which have been slightly bevelled, this is sutured proximally and distally to the artery by a simple over-and-over stitch using no 5 0 arterial silk Blood-flow through the main artery distal to the occlusion was successfully re established in 37 of the 40 limbs in which this technique was used Success was determined by arteriography or by the return of palpable pulses distal to the block It is particularly significant that none of these patients was made worse by the operation The indications for intervention were severe intermittent claudication and gangrene All the patients with rest-pain and claudication were relieved immediately and have remained well for periods up to eighteen months The results in patients with gangrene were just as impressive In a paper just published Crawford et al[4] confirm that they have found the by-pass operation better than other methods, particularly in patients with relatively long occluded segments If its further trial is equally encouraging, the by-pass operation may indeed prove to be so notable an advance that the indications for operating on occluded arteries may become much wider

UNEXPLAINED OSTEOLYSIS

THE mysterious gradual absorption of a single bone, or of a group of bones, is a rare condition found chiefly in young adults, often after a fracture The ultimate result may be the complete disappearance of part of the skeleton Krikler[5] has recently recorded a case of this kind · a coloured man of 35 said that five years before attending hospital several of his toes shrivelled up and disappeared Such a condition, as Engle and Morton[6] have pointed out, is common in the unshod native, but is usually related to local infection or trauma In Krikler's patient full investigation failed to show an underlying cause, and it seems likely that this is an example of this " idiopathic osteolysis " Gorham et al[7] were able to find only 16 examples of disappearing bones reported in the literature, and they added 2 examples from their own experience. In the recorded cases, trauma seemed largely incidental, although sometimes a pathological fracture was the first indication of bone resorption When a number of bones were affected, they were usually in the same limb Progress of the condition was slow and variable, sometimes it stopped, but occasionally it ended fatally Biopsies suggest that a common feature is an overgrowth of thin-walled blood-vessels, and the osteolysis may be directly related to this angiomatous change The picture of complete and very localised destruction of bone accords well with this view, and seems to distinguish the condition sharply from the post traumatic atrophy first described by Sudek[8] There are good grounds for accepting massive osteolysis as a distinct clinical entity, although its cause and its relation to other forms of osteolysis are obscure

Public Health

OLD FOLKS AT HOME

The Kinds of Help They Need *

Sir Selwyn Selwyn-Clarke
K B E, C M G, M C, M D Lond, F R C P,
D T M & H, D P H
A PRINCIPAL MEDICAL OFFICER, MINISTRY OF HEALTH

By far the larger proportion of old people remain in their own homes indeed less than one in ten are accommodated in long-stay hospitals or in welfare hostels This is as it should be . for it is both natural and commendable that, at the end of their lives, old people should want to remain in surroundings familiar to them We must recognise, however, that many can do so only on one condition—namely, that when their powers are failing they receive appropriate help

FAMILY, NEIGHBOURS, AND VOLUNTEERS

In such circumstances we think first, of course, of families and relatives But families are on the average much smaller than they were fifty years ago and the individual responsibility for caring for elderly parents is correspondingly heavier Moreover, sons and daughters often go to live in some other part of the country or go abroad, leaving the old person all alone

A second line of defence is the good neighbour In times of full employment far fewer persons stay at home, and many wives do part time work in factories and thus have less time for the neighbourly turn to the old person living next door Nevertheless an immense amount can still be done by voluntary effort, both individually and through old people's welfare committees and Darby and Joan clubs which provide means whereby the aged can enjoy social intercourse and be helped by and help each other

In Swindon the different streets have been assigned to volunteers who make themselves responsible for visiting —once, twice, or more often, every week—all the old people in those streets who have expressed a wish to be visited This ensures at the very least that no old person, living by himself and falling suddenly ill, will lie helpless for days till death brings release Needless to say, not everyone wants to be visited by a stranger, however well-wishing , but most old people welcome visitors who are obviously out to do their best to bring a ray of sunshine into a drab and lonely place and who are not snoopers or busybodies A visit “ after hours ” is especially appreciated, and many an old person is thankful for the kindly gesture involved in the visitor making an evening cup of tea, helping grannie to get to bed, filling the hot-water bottle, putting the commode handy, lighting the safety night-light, and so on Similar visits in the earlier part of the day enable old people with a tendency to become bed-bound to get washed and dressed and into a comfortable chair or even on to a sunny porch Help with the week's shopping, with change of linen and laundry, or in getting to the old people's club, the church, the chapel, or the cinema, can do much to brighten an old person's existence

In some places that I have visited, the Women's Voluntary Services, Women's Institutes, British Red Cross Society, St John Ambulance Association, and various religious and other bodies have joined together to help to bring comfort to the aged Some voluntary bodies and local authorities arrange holidays for old people in the country or by the sea , for example, in Devonshire there is a system whereby some hotels at seaside places are willing to take old people at reduced rates out of season

In some circumstances, despite all the help that can be mustered, it is no longer possible for the old person to remain at home by himself Sometimes, if the house is big enough, the old person can take in a family, who, in return for free lodging, attend to his needs In other cases—as has been done so successfully in Exeter and in a few other towns, often with help from the National Corporation for the Care of the Aged—families are persuaded to “ adopt ” an elderly person and provide board and lodging and care in their spare room at a cost which can be met by the old person, assisted, perhaps, where necessary by the National Assistance Board

I have purposely started with examples of what can be achieved by voluntary effort, because I am convinced that there is a vast reservoir of this still waiting to be tapped After all, even as things stand, more than nine out of every ten persons of pensionable age reach the end of their lives without having to go to live in hospitals and welfare hostels , and, if their needs were better known, a great many younger people would want to help them to avoid a painful transplantation to unfamiliar surroundings at a period of life when it is difficult, if not impossible, to strike fresh roots

HEALTH VISITOR, HOME HELP, AND DISTRICT NURSE

There comes a time, however, when the old need rather more help in their homes than can be supplied from voluntary sources It is at this stage that the health visitor does such valuable work, although the earlier she is on the scene the better She can give friendly advice and encouragement which will prevent an old person from becoming house-bound and cut off from contact with his fellow men She can put him in touch with the various voluntary and local-authority bodies who are in a position to help him in one way or another Sometimes all he needs is the services of a chiropodist, and these can often be provided through an old people's club The health visitor can make sure that the old person does not take to living only on tea and bread and margarine and develop malnutrition She can see whether he needs assistance in keeping his house and himself sweet and clean, and she can arrange for a home help if necessary An efficient but warm-hearted home help can be a wonderful comfort to the old, especially those living alone

The health visitor will do her best to keep the old person up and about, so that he does not become bed bound and is less likely to suffer from chronic constipation, mental deterioration, and incontinence Should he fall ill, she can keep his family doctor advised and, at the doctor's request, call on her nursing colleague for her skilled assistance The district nurse may need to arrange for the loan of bedding, sickroom equipment, and so on, all the time cooperating closely with the patient's doctor Often, too, a patient who returns from hospital will need for a time help from a district nurse and/or a home help Here, the hospital almoner comes into the picture, making sure that the necessary arrangements are in train before the patient is discharged

In providing special accommodation for the old, the emphasis should always be on enabling them to remain active members of the community and on preventing their segregation from children and the young and middle aged In some county boroughs I have seen housing schemes where, in the midst of family houses, there and bungalows for old people, or ground floor flats, the upper floors being allocated to young families who can give a helping hand to the old person in an emergency In others I have seen, in the middle of a housing scheme, a group of single storey bed sitting-rooms (with individual kitchenettes and bathrooms) for single and married old folk, with a warden's house

---

* From an address at the annual meeting of the Exeter Maternity and District Nursing Association on June 9, 1955

adjoining so that the old person has someone on the spot to help him, if need be. Yet again I have seen this bungalow arrangement with a sick bay to which an old person can go temporarily when it is unwise to leave him alone in his house and where he can receive nursing care at night if the occasion demands. I believe certain housing authorities have worked on a basis of reserving one tenth of their housing for old people.

There comes a time, however, when despite all manner of domiciliary help an elderly person of slender means can no longer stay the course and needs to go to a welfare home. Wherever possible, this home should not be far away from where he lived so that he can visit or be visited by his family or friends and will not feel cut off from familiar sights and sounds.

In determining when this stage is reached the health visitor plays a particularly important part. She contacts the welfare officer directly or through the medical officer of health, taking special pains to keep the aged person's doctor informed and to consult his wishes.

ILLNESS AND DISABILITY

Where an old person is ill the district nurse, with the help of relatives, neighbours, voluntary workers, and a home help, is often able to tide over the period of illness and to nurse him in his home. Similarly, some welfare homes have sick-bays where a patient can be looked after by the district nurse if he requires more elaborate nursing than the staff of the welfare home are themselves able to give. But when the nature of the illness or the social conditions necessitate hospital care and the family doctor thinks this the only satisfactory means of dealing with the situation, the patient will be removed, with his consent, to a hospital.

Nowadays, happily, old people do not go to these hospitals to die. Quite a large proportion receive active geriatric treatment, with physiotherapy and occupational therapy, and are restored to health and home once more. A remarkable change is taking place in many if not all of the old poor-law infirmaries now used for elderly chronic sick patients, and the dread of entering them is rapidly disappearing.

Some of these hospitals—e.g., the Cowley Road Hospital at Oxford—have a department called a day hospital to which frail ambulants and mentally and physically sick persons of pensionable age go for the day to receive physiotherapy, occupational therapy, and a nourishing midday meal, returning to their homes in the late afternoon. A day hospital of this nature affords great relief to relatives, especially when the old person suffers from mental confusion and cannot safely be left alone in an ordinary house. Once more, if an elderly sick person has to be admitted to a long stay hospital, it is important that this should be as near as possible to his own home if he has any relatives or friends who might visit him.

Where the patient has been in hospital for a considerable time, he may, of course, no longer have a home to which he can return; and then a place has to be found for him in part III dormitories of a joint-user institution, or in one of the welfare homes which are increasingly being built in the vicinity of hospitals, thus reducing the patient's fear of the unknown and increasing the chance of his keeping in touch with friends and family.

Many old people show mental changes, for mental confusion may be just as much an affliction of old age as hardening of the arteries; but it is well to remember that admission of an elderly person to a mental hospital no longer means that he will spend his remaining days there. At least half the patients over 65 years of age admitted to mental hospitals suffer from straightforward depressive illness that can be treated, and it is an encouraging fact that 9% of patients over 65 are discharged within six weeks, 31% within six months and 38% within twelve months.

Incidentally a diet rich in protein and vitamins has sometimes worked wonders in the first few days in the treatment of senile, confused patients who have had to enter a hospital, pointing the way to one of the preventive measures that can be taken to forestall, or at least postpone, the onset of senile degenerative changes. Keeping the elderly person ambulant (ensuring chiropody services) and in contact with human interests through clubs and outings are additional means of retaining mental alertness and a joy in living.

CONCLUSION

In this address I have tried to emphasise three things.

The first is the need for more voluntary effort on behalf of the elderly sick and the aged requiring care. I am certain that many more people would give such help if they knew how much good they could do.

The second, related to it, is the need to develop domiciliary aid of all kinds, both voluntary and statutory.

Thirdly, in planning living conditions, we must do all we can to keep the old people of our community integrated with the younger ones, and not to segregate them in institutions and hospitals unless or until this is unavoidable.

To these points I would add a fourth—namely, the need to coordinate in each area all the different ways in which we are trying to help the aged—so that whatever we do shall be done intelligently and as well as we can do it.

Fog

There has been no evidence that the fog which covered many parts of the country last week has had an appreciable effect on mortality or morbidity. Certainly nothing comparable to the 1952 experiences has been reported. In London calls on the Emergency Bed Service were about the usual for the time of year. Special measures for the care and investigation of fog victims in London had been prepared by the Medical Research Council but only a few patients were admitted to the beds set apart for fog casualties at St. Bartholomew's Hospital, the Brompton Hospital, Hammersmith Hospital, and the London Chest Hospital. At Barts bottles of ammonia were left open in some of the wards; we referred earlier[1] to the plans for investigating the use of ammonia as a possible means of preventing damage to the lungs by acid vapours.

Epidemic Respiratory Illness in Children

On Christmas Eve there was a sudden demand for beds in the children's hospitals in Liverpool, and special wards had to be opened at Fazakerley Infectious Diseases Hospital to deal with the infants requiring admission. We are indebted to Dr. Andrew Semple, medical officer of health for Liverpool, for the following account of the outbreak so far.

General practitioners and pædiatricians in the area began to see many cases of acute respiratory infection over the Christmas holiday. The condition was described as an acute bronchitis, bronchiolitis, or pneumonia, almost entirely confined to children under eighteen months. In Alder Hey Hospital alone, up to Jan. 3, 57 cases were admitted, 42 with a diagnosis of bronchopneumonia and 15 with a diagnosis of acute bronchitis. Most of the children were not very ill by the time they settled down in hospital, but practitioners reported that in the early stages there was striking evidence of acute respiratory infection. The number of notifications of acute primary pneumonia for the week ending Jan. 7 was 36, compared with 17 for the corresponding week last year. Up to Jan. 3 about 130 cases had been traced and by Jan. 9 the Liverpool public-health department knew of about 230 cases.

Although many children have been admitted to hospital, there are indications that a considerable number more are being adequately treated at home. 1 of the children involved died, and post-mortem specimens have been sent to the M R C Virus Reference Laboratory, together with throat-washings, stools, and blood from acute cases It is generally felt this is probably a virus infection It has appeared in all parts of the city The acute infection seems to be mainly confined to babies although there are some indications that preschool-children over the age of 2 are also affected, and the public-health department is following up the contacts of children admitted to hospital

---

[1] *Lancet*, 1955, ii, 975.

In Sunderland about 100 children have been treated at the Children's Hospital in the past month for an epidemic respiratory infection [1] 40 of them were still in hospital on Jan 9 There was a similar epidemic in Sunderland two years ago

Statistical Review of England and Wales

The medical tables of the Registrar-General's Statistical Review of England and Wales 1954 [2] were published last month Some of the main figures had already been published in earlier returns [3] and in the annual report of the Ministry of Health [4] The new volume gives details of deaths from all causes and notifications of infectious diseases in 1954, by age, sex, area of residence, and time of year

Of the total infant mortality in 1954, the loss in the first week after birth accounted for nearly 60%, and the loss in the first three months of life for over 80% The death rate of children aged 1–4 years in 1954 was 0 94 per 1000 population In 1953 it was 1 18 and in 1920 it was 12 08—a decline of over 90% in thirty four years

Deaths resulting from accidents in the home and residential institutions continued to increase, and numbered 6617 Of this total 4790 (72%) were deaths of old people aged 65 or over 4188 of all such accidental deaths were due to falls Deaths in the home and residential institutions due to accidental poisoning by domestic gases continued to increase —from 461 in 1952 and 554 in 1953 to 614 in 1954 There were 597 deaths due to accidents caused by fire and explosion of combustible material 687 children under 5 died in accidents in the home and residential institutions—compared with 731 in 1953 Of these, 250 were certified as due to inhalation and ingestion of food and 182 to accidental suffocation in bed or cradle

Also published recently was the text volume of the Registrar General's Statistical Review for 1952 [5] This is the official commentary on the civil and medical statistics for 1952, already published

SKIING INJURIES IN NOVICES

J A Williams
M B Birm, F R C S
LATE CAPTAIN, R A M C

I describe here skiing injuries, particularly those to the knee, among 2000 British troops and their families in Austria during the season of 1952–53, and refer to a follow-up of knee injuries sustained in the previous season

Most of the patients were troops learning to ski, the injuries were sustained from one day to twelve weeks after they had first worn skis

The majority of the injuries were strains of the knee or ankle, or both (see accompanying table) There were 100 such injuries, whereas there were only 5 cases of fractured tibia and fibula and 6 cases of undisplaced fracture of the ankle Austrian practitioners at ski centres agreed that this was a typical distribution of injuries in novices, experienced skiers tend to sustain fewer and more severe injuries

TYPES OF SKIING INJURY

Type of injury	Cases	
	No	Percentage of population at risk
Strain of knee	54	2 7
Strain of ankle	46	2 3
Fractured tibia and fibula	5	0 25
1st deg Pott's fracture	6	0 3
Dislocated shoulder	2	0 1

Knee Injuries

Of the 54 patients with knee injuries, I examined and treated 44 All but 1 were followed up for from three to six months after injury The injuries, which differed from one another only in the degrees of severity, were strains of the internal lateral ligaments of the knee joint No patient had a tear of his internal semilunar cartilage

Mechanism of Injury

There were two common causes of injury, both of which are more likely to operate in the inexpert than in the expert skier (1) crossing the skis when attempting a Stem-Christiania or a "snow-plough" turn (20 patients), and (2) divergence of skis when running into deeper snow (15 patients) In both groups there was a combination of rotation and abduction strains, the rotation being internal in the first group and external in the second, in all cases the abduction strain was apparently the greater force Injury usually did not take place with the patient at speed, but was a gradual strain caused by the falling body-weight abducting and rotating the knee, the foot being firmly fixed in the snow by the ski No patient had knee strain while attempting a Telemark turn, which was not used in skiing instruction

Many patients in the first group who suffered internal rotation of the knee had strains of the lateral ligament of the ankle, but no patient in the second group had any associated ankle injury

Diagnosis

In all cases pain was referred to the medial side of the joint, and there was tenderness in the joint line over, or anterior to, the internal lateral ligament Patients examined some days after the injury were tender in front of the lower attachment of the ligament, and in severe cases bruises were visible at this point The mastia). He had a typical eunuchoid facies, no facial hair, scanty pubic hair, and very fine brittle, and scanty scalp hair. His voice was high pitched and tended to squeak when he became excited. His skin was dry and scaly, with local infection on his face. His blood pressure in the sitting posture was 160/105 mm Hg, and his penis was very small and retracted into the pubic fat, his right testis was undescended, and his left testis was small. At a life assurance examination a short time before he had been graded as a second class life and accepted only on a greatly increased premium.

Treatment and Progress.—Treatment was started early in 1952 with intramuscular testosterone propionate 50 mg twice weekly. His blood pressure was again checked before the start of treatment and found to be still 160/105 mm Hg in the sitting posture. This produced an immediate and very dramatic improvement in all his symptoms. He became energetic, cheerful, keen on his work and hobbies, and very active, and evinced an interest in women for the first time. This treatment was continued for a month and then reduced to 50 mg weekly supplemented by 10 mg of methyl testosterone by mouth daily. After five months of this treatment a striking change had taken place. Facial hair had begun to grow, his voice had deepened and lost its squeakiness, and he had lost over $1^{1}/_{2}$ st in weight, the fat all having disappeared from his breasts, hips, thighs, and lower abdomen. His penis was larger and had emerged from the pubic fat, and he was having erections weekly. His right testis had descended into the scrotum and increased in size. His scalp hair had changed completely, being thicker, stronger, and more profuse. His skin rash had disappeared, and his skin was less coarse. His personality had changed, and he was more ambitious, had more drive and energy, and was cheerful and no longer felt shy and inferior. His blood pressure in the sitting posture was 155/100 mm Hg. The treatment was then changed to testosterone phenyl propionate 50 mg by subcutaneous injection, which the patient gave himself at intervals of four to eight weeks over the next three years.

Follow up.—All the changes have been maintained except the loss of weight (he weighs nearly 13 st again), but the distribution of the fat is now typically of the obese masculine type. His penis is now $4^{1}/_{2}$ inches long on erection and not retracted when flaccid. He has occasional nocturnal emissions, usually six or seven days after his injection. His blood pressure has fallen to 140/90 mm Hg in the sitting posture, and at a recent life assurance examination he was classified as a first class life and accepted at normal rates. He has been promoted to managing director of his firm and is going to marry. No ill effect has so far been detected after four years' treatment.

Discussion

This case shows several rather unusual features: the presence of a congenital abnormality of the genito-urinary tract; the late age at which the treatment was started, the very dramatic changes, especially psychological, the effect on the scalp hair (its changed character may have been due to hormonal therapy or to the psychological changes), and the lowering of the blood pressure. This last change is the most difficult to explain. There seem to be three possibilities: (1) it was purely coincidental and would have occurred in any event, (2) it was due to relief of the psychological tension, and (3) the hormonal therapy exerted a direct effect on it through the pituitary gland or through the adrenal glands.

New Inventions

A PLASTER OVERBOOT

A WALKING-PLASTER requires some form of protective cover or attachment. There are many different types available, these include metal or wooden rockers, 'Sorbo' rubber heels, Bohler irons, sections of rubber tyres, canvas overboots, and the Ludun boot. Most of these, however, have one or more disadvantages:

(1) The appliance may cause an abnormal gait, which often persists after the plaster cast has been removed.

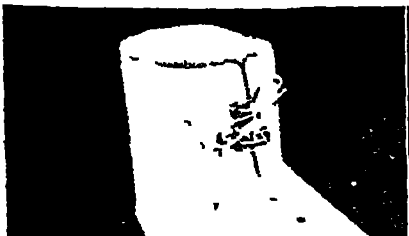

Fig 1—P V C boot and sponge-rubber insole

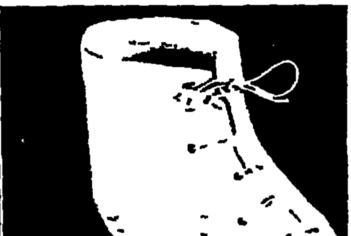

Fig 2—Latex boot and insole of felt covered cork

(2) The appliance offers no protection and the plaster gets soft in wet weather.

(3) The appliance may tear the bed clothes.

(4) The appliance may be difficult to put on correctly.

(5) The appliance may be intrinsically expensive or difficult to manufacture, and further expense is incurred by the use of plaster bandages to attach the appliance firmly to the cast.

To obviate these disadvantages a plaster overboot was designed and made from polyvinyl chloride (P.V.C.).

This boot (fig. 1) is cheap, light, waterproof, easy to slip on and off, and æsthetically not unpleasing to the eye. It enables the patient to simulate a heel-and-toe gait, and additional springiness is gained by the use of a sorbo rubber insole. The material is durable, as is shown by the fact that the boot has been in continuous use for eighteen months with very little sign of wear on the sole. If it does wear thin, the base of the boot can be redipped into liquid P.V.C.

The process used in making the boot is as follows:

(1) Preheat mould to 160°C. Dip the canvas webbing in the P.V.C. and fit to the mould, and then pregel for two minutes in an oven at 110°C.

(2) Dip again for 45 seconds and pregel in the oven for 5 minutes at 110°C.

(3) Redip the base only for 2 minutes and stove in oven for 25–30 minutes at 160°C.

After the P.V.C. prototypes were put on trial, a simpler boot was developed (based on the same principles), this boot can be made quite easily in any hospital workshop. Instead of P.V.C. latex is used. The plaster cast, covered with stockinet, is dipped into latex and then dried at 120°C for 10 minutes, this is repeated once for a small boot and twice for a large boot. After drying, an ordinary crepe sole is stuck on to the base because the latex does not grip as well as the P.V.C. This boot (fig. 2) is slightly more bulky in appearance and slightly heavier but costs a little less. The price of one boot is about 5s., and the total working-time required to manufacture one latex boot is 15 minutes. It has been found by experience that only four sizes of over-boot are necessary, and from this small range an overboot can be selected to fit any plaster.

I am grateful to Messrs Pryor & Howard for making the P.V.C. prototype, Mr W. Tuck, workshop manager at the Royal National Orthopædic Hospital, for making the latex boot, and Mr Robert J. Whitley, F.R.P.S., for the photographs.

HAZARDS OF NUCLEAR AND ALLIED RADIATIONS

The report[1] was published on Tuesday of the committee appointed by the Medical Research Council to consider the medical aspects of nuclear radiation, including the genetic aspects The committee was set up under the chairmanship of Sir Harold Himsworth, F R S because of the widespread concern about the possible long-term effects of test explosions of nuclear weapons This is however only one aspect of the hazards to man of ionising radiations, and the committee's report deals with present knowledge of the whole subject

An attempt is made to assess the contribution from each source of radiation to which the inhabitants of this country are at present, or might in future, be exposed The most outstanding finding is that by far the largest contribution is made by diagnostic X-ray examinations, and that examinations of a relatively few sites of the body account for most of the population dose, examination of the chest is relatively unimportant The results of an investigation which is still in progress (a preliminary report by Mr Osborn and Mr Smith appears on this page) suggest that this source provides a gonad dose of 22% additional to that received from natural sources, and that this figure may well be an underestimate It is concluded that present practice in diagnostic radiology should be reviewed to clarify the indications for the different special examinations now being carried out

The estimated population doses of radiation to the gonads are as follows -

Source of radiation	*Approximate dose to gonads as a percentage of natural background*
Natural background	100
Diagnostic radiology	at least 22
Radiotherapy	?
Shoe-fitting	0 1
Luminous watches and clocks	1
Television sets	much less than 1
High altitude flying	insignificant
Occupational exposure	
Radiology and industry	at least 1 6
Atomic Energy Authority	0 1
Fall-out from test explosions	less than 1

The inhabitants of this country may receive in the next 50 years, from nuclear weapons already exploded, about 0 02% to 0 04% of the radiation that they will receive during the same period from natural sources If the firing of bombs were to continue indefinitely at the same rate as over the past few years, there would be a build-up of activity, gradually reaching a plateau in about a hundred years, which would give the average individual a dose over a period of 30 years of about 1% of what he would receive in the same period from natural sources The individual and genetic effects of such a dose of external radiation would be insignificant

The most important constituent of fall-out from bombs is strontium 90 which, if ingested, is concentrated in bone where it may give rise to destructive changes including cancer In relation to strontium 90, the committee concludes that " . at its present level, no detectable increase in the incidence of ill-effects is to be expected " The maximum permissible concentration in bone allowed for those who might have to deal with this substance is 1000 micromicrocuries per g of calcium in the skeleton For the general population, however, the committee believes that the figure should not exceed 100 and that immediate consideration would be required if the level showed signs of rising greatly beyond 10 At present, measurements in this country show that the highest concentration in bone is about 1 micromicrocurie and if the present rate of firing continues, this level may be increased tenfold in the course of several decades

The committee sponsored a detailed study of the incidence of leukæmia among over 13,000 patients treated with X rays during the past 20 years for ankylosing spondylitis The results suggest that there is an increase in the small chance of developing leukæmia after exposure to a total dose of radiation which might, in exceptional circumstances, be met with in civilian life It is not certain, however whether any increase would occur if the same dose were spread over many years

The committee concludes that, with proper safeguards, exposure in peacetime can be maintained at levels which can be accepted by the individual without undue concern either for himself or his offspring But since genetic effects are eventually distributed throughout the whole population, a relatively high dose to a fraction of the community can only be offset by a correspondingly low dose to the remainder, and it is therefore important for those not occupied in work involving radiation to receive as little as possible The committee declares ' Our present knowledge does not justify us in naming any specific figure as a limit for the average dose of radiation which might be received by the population as a whole It is highly desirable that such a figure should be named as soon as possible, and we understand that the International Commission on Radiological Protection has this matter under consideration "

THE GENETICALLY SIGNIFICANT RADIATION DOSE FROM THE DIAGNOSTIC USE OF X RAYS IN ENGLAND AND WALES

A PRELIMINARY SURVEY

S B Osborn
B Sc Lond, A Inst P
PRINCIPAL PHYSICIST, UNIVERSITY COLLEGE HOSPITAL, LONDON

E E Smith
B Sc Lond, A Inst P
DEPUTY DIRECTOR, RADIOLOGICAL PROTECTION SERVICE
DOWNS HOSPITAL, SUTTON, SURREY

In recent years, increasing attention has been paid to the genetic consequences of exposure to ionising radiations, and various attempts have been made to estimate the maximum accumulated dose, in excess of natural background, that can safely be received by human beings Such estimates have been based largely on experiments on fruit-flies (*Drosophila*) and mice, and considerable speculation has attended the extrapolation to man

At present, because of uncertainty about the proportion of observed spontaneous gene mutations which are induced by radiations, the permitted exposure is often expressed as a percentage of the background dose rather than in a definite number of röntgens rems, or rads

The most recent pronouncement on this subject by the International Commission on Radiological Protection (1956) states

> " Hitherto, the Commission has occupied itself with workers in hospitals the new atomic industries and research institutions, but has now assumed responsibilities in relation to much larger groups of persons, or whole populations, which might be exposed to radiation by radioactive materials, either natural *or* artificial, in very small quantities in water or food, as well as irradiation from radioactive materials in the atmosphere and contamination of the earth's surface Its recommendations have therefore been extended to a consideration of these larger populations
>
> " Unfortunately information on the genetic and other effects on populations is extremely scanty and the Commission has not, *therefore, felt* it possible to lay down precise doses but has indicated that for the whole population it would be prudent to limit the dose of radiation received by gametes from all

Reviews of Books

Control of Disease in the Tropics

T H DAVEY, O B E , M D , D T M , and W P H LIGHTBODY, C B E , L R C P , School of Tropical Medicine, Liverpool London H K Lewis Pp 408 47s 6d

THE appearance of a new textbook on the preventive aspects of tropical disease is an event of great importance to thousands of doctors who work in the tropics, and to the many students who take courses of tropical medicine and hygiene each year The authors have set out the principles of control and prevention, disease by disease, systematically, succinctly, and clearly

Helpful diagrams illustrate transmission cycles There are sections on housing, water supplies, disposal of human and animal wastes, nutrition and vital statistics An appendix gives detailed information on practical procedures The book is well produced, on good paper and well bound, at a reasonable price (we note, without regret, the omission of the customary statement that an insecticide has been applied in the binding)

A book like this must necessarily be condensed and didactic, and it might have been an advantage to include references on important subjects, for more detailed reading, at the end of each chapter When referring to the only standard text book on a subject (even by authors whose opinions are so highly respected), the reader may expect at least a mention of views which, if not yet universally accepted, are widely discussed and acted on A conspicuous omission is the assessment of malarial endemicity by calculation of the daily rate of infected bites—a method in increasing use, and about which any tropical practitioner might need help

In the control of insect borne diseases, one or two recommendations err on the side of idealism For example, few villagers will cooperate in bi weekly "dry pot" days, whereas a weekly day is comparatively easy to achieve Again, the nuisance value to European women of thigh length mosquito boots and their suspensory apparatus is an item seriously to be weighed against the extra protection afforded over and above that of the efficient modern antimalarial prophylactics Neurosis is commoner than malaria as a reason for European women leaving the tropics, and taking their husbands with them

In the control of simulium, dicophane (D D T) is not necessarily best applied as an emulsion The most remarkable results so far, in Saskatchewan, were achieved with a solution The implications of this experiment, in results, economy of dicophane, and sparing of fish life, are important

We welcome and commend this book, which fills a gap in the ranks of medical textbooks

Doctor's Offices and Clinics

Medical and Dental PAUL HAYDEN KIRK and EUGENE D STERNBERG New York Reinhold London Chapman & Hall 1955 Pp 218 96s

THE post-Danckwerts interest-free loans for group-practice premises are likely to have, over the years, a profound effect on British general practice The move towards group practice will be intensified, and general practitioners, secure in good buildings of their own, will be able to face the future with increasing confidence But the emphasis must be on *good* buildings hence, the growing importance of the design of group-practice centres

It might be supposed that the ideas of American doctors and architects would be far removed from the prospects confronting their English counterparts in Bow or Bromley yet, strangely enough, similar problems have produced similar answers Most American cities are now undergoing decentralisation People are moving out from up-town apartments to low-density suburban residencies So the doctors leave their 'offices" in commercial blocks in the centre and build for themselves special-purpose buildings in the new residential suburbs As in the English country towns in the past twenty or thirty years, the economics of the situation encourage group practice The American general practitioner is as concerned as the English one to keep down costs The result is that the architectural solutions have a direct relevance to British needs It is more than fortuitous that the buildings illustrated in this book are very similar to the group-practice centres provided by the Nuffield Provincial Hospitals Trust at Harlow New Town Economy, efficiency, and a homely friendly atmosphere are combined in one-storey buildings which yet manage to look purposeful and distinguished This is a book to be studied carefully by those contemplating the construction of their own group-practice centre It could usefully be read in conjunction with the Nuffield survey of *Good General Practice*,[1] as a necessary occasional corrective But it is surprising how seldom such correction is necessary

Genetics in the Atomic Age

CHARLOTTE AUERBACH, PH D , D SC , Institute of Animal Genetics, University of Edinburgh Edinburgh and London Oliver & Boyd 1956 Pp 106 8s 6d

THIS is a readable and amusing little book by a geneticist who has made important discoveries in the chemical induction of mutations Her aim is serious it is to give the reader enough of the background of genetics for him to appreciate the dangers of an increase in the exposure of human germ-plasm to radiation and this is well done There is no unjustified "scare" about the dangers of radiation, and the present uncertainty and ignorance of the size of the effects in man is made clear But Dr Auerbach also emphasises that there is no "safe dose," that every increase in radiation will bring some increase in mutations, and that the very great majority of these will be harmful She is pessimistic about the possibility of men and women taking control of their own evolution by speeding the elimination of harmful mutations from the population, and encouraging the spread through the population of the very occasional useful mutation

The Dynamic Equilibrium of Body Proteins

Hæmoglobin, Plasma Proteins, Organ and Tissue Proteins GEORGE H WHIPPLE, M D , professor of pathology emeritus, University of Rochester, New York Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1956 Pp 68 23s 0d

THIS book sets out in the barest possible terms the facts that show that the body-proteins, all of them, exist in a dynamic equilibrium with each other The plasma proteins and tissue-proteins are constantly interchanging, and Professor Whipple thinks that, for this to proceed breakdown only to polypeptide level is needed The earlier work with injection and withdrawal of plasma proteins, and the later work with material labelled with C^{14}, are briefly mentioned The effect of inflammation on the synthesis of hæmoglobin, and the fact that the placenta will allow proteins to pass from mother to fœtus, are among other topics He emphasises the key position of the liver

It is interesting to see from this book the topics and results that Whipple considers most important in his experimental work on protein metabolism that began thirty years ago But it is hard to know to whom such an outline is addressed, it is much too brief for physicians or medical students, and investigators in this field will surely be familiar with all the points

Blood Group Substances

Their Chemistry and Immunochemistry ELVIN A KABAT departments of microbiology and neurology, College of Physicians and Surgeons, Columbia University New York Academic Press London Academic Books 1956 Pp 330 64s

THIS volume collects together and comments upon an immense amount of information on the quantitative immunochemistry of the blood-group substances, and it gives a remarkably extensive bibliography The information is technical in the extreme and no concessions are made to the man who knows only a little about the immunology of blood groups, still less to general readers The latter can only turn over the pages in wonder that so much is known about the immunochemistry of the blood groups, and that it has had so little application to everyday work with the blood groups To the small band of initiates, this book will undoubtedly be useful sources additional to the natural background, to an amount of the order of magnitude of the natural background."

---

[1] Taylor, S Good General Practice London 1954

In these circumstances it is necessary to know the average background exposure and the average dose now being received from all the additional sources of ionising radiation to which people are exposed. Here we are concerned only with the radiation received by the "genetically alive" fraction of the population—i.e., predominantly young people, from their conception to the age at which their last child is conceived. This requires a knowledge of vital statistics, some aspects of which are at present incomplete.

Spiers (1956) has assessed the annual dose received by the gonads from all sources of natural radiation, the most important of which are cosmic rays, gamma rays due to the radioactivity of the environment, and beta and gamma rays from the naturally radioactive isotope of potassium in the body. This dose varies in different localities (Spiers and Griffiths 1956) and countries (Sievert 1956). The average values for Leeds (0·090 rad per annum for females and 0·100 rad per annum for males) are used here. If the high radon concentration reported for London by Anderson et al. (1954) is found to be fairly general, these values will have to be increased.

The sources of additional exposure to ionising radiation are numerous, and all have been introduced in the last fifty to sixty years. They include diagnostic and therapeutic radiology, luminised articles (such as clocks and watches), television and other high-voltage cathode-ray tubes, high-voltage rectifying valves, shoe-fitting fluoroscopes, industrial radiology in all its aspects, research equipment of many kinds, and nuclear weapons and power. Of all these sources there is no doubt that, in this country at least, diagnostic radiology has been by far the most important up to now.

We describe here an attempt to estimate the genetically significant dose received by the population of England and Wales from this cause. This has been done previously for Australia (Martin 1955), for the U.S.A. (Billings et al. 1955, Clark 1956), and for the United Kingdom (Stanford et al. 1952, Farmer 1955). Our data, although still far from complete, are thought to be more comprehensive than those hitherto available.

Methods

In order to make this estimate, we must know how many X-ray diagnostic examinations are made each year and the distribution of the various types of examination in terms of age and sex. We must also know the average technique for each type of examination in so far as it affects the dose delivered to the gonads. Finally, we must know the vital statistics of the community as regards the conception of children.

Vital Statistics

Previous published work has estimated the radiation dose received by the gonads up to the age of 30, the approximate mean age of reproduction. We prefer the method of Farmer (1955), in which the dose received by any person from conception up to a given age is weighted according to the probability that he or she will conceive a child at that age.

Fundamentally, the work described here is an attempt to ascertain whether the number of genetic mutations induced by the radiation used in diagnostic radiology is significant or not. For this we have assumed that the number of radiation-induced mutations added to the population at the birth of a child is proportional to the total radiation dose received by the gonads of both parents from the time at which each of them was conceived up to the time at which their child was conceived. Though such a calculation can be made simply for a single individual, when a whole population is concerned it can only be done statistically. We have accordingly weighted the dose accumulated by the gonads of a person from conception up to a given age according to the probable number of children to be born to a person of that sex at that age (the "risk of parenthood") taken from general population statistics. A dose so weighted becomes a new unit, which we call the "röntgen equivalent genetic" or "reg," and radiation doses weighted in this way we call "genetically significant radiation doses." The accumulated dose received by the gonads from natural radiation has been calculated similarly to enable a direct comparison to be made.

TABLE I—STATISTICS OF PARENTHOOD

Age (yr.)	Risk of parenthood *		Risk of subsequent parenthood †	
	Male	Female	Male	Female
0–14	0	0	2·177	2·216
15–19	0·016	0·110	2·169	2·161
20–24	0·320	0·673	1·996	1·769
25–29	0·654	0·607	1·505	1·054
30–34	0·507	0·445	0·895	0·514
35–39	0·315	0·222	0·439	0·180
40–44	0·182	0·065	0·176	0·036
45–49	0·065	0·004	0·052	0·002
50–54	0·020	0	0·010	0
55 or more	0	0	0	0

* Risk of parenthood is the average number of children to be born to a member of the community during the period specified.

† Risk of subsequent parenthood is the average number of children expected to be born to a member of the community after the mid-point of the period specified.

When the genetically significant radiation dose is summated for the whole of a person's life, or is summated over a given period for a group of people or a whole population, it is numerically equal to the dose received by a person at the given age multiplied by the probable number of children to be conceived by that person subsequently (the "risk of subsequent parenthood"). Since this method of calculation is arithmetically easier, it has been used.

The "risk of parenthood" for females is assessed from statistics published by the Registrar General (1955) for 1953 by using only the figures for live births, whether legitimate or illegitimate. For males the required information is available only for 1938 (Royal Commission on Population 1950). Women certainly tended to have children at an earlier age in 1953 than in 1938, and, since the relative age of women and men at marriage has not changed appreciably, it is assumed that the tendency is present to the same extent in men, and the 1938 figures have been corrected accordingly. The data used are given in table I.

It is implicitly assumed that all hospital X-ray patients (except those undergoing salpingography) are normally fertile people whose "risk of parenthood" is the same at any given age as that for the population at large. This may not be wholly true, but any deviation is likely to be small, and in any case we have no information on which to base a correction. Salpingography, being normally undertaken to assist in the diagnosis of infertility, must be treated differently because all the women thus examined are married and anxious to have children. It is assumed that, on the average, each woman so examined subsequently bears one child.

Annual Number of Examinations

The number of diagnostic X-ray examinations made each year at present is given in table II, which shows that the great majority of them are made in National Health Service hospitals. The source of the figure is the annual reports of the Ministry of Health. For 1951 and 1952 these give the "number of examinations," and for 1953 and 1954 the "units of work done." The known increase for 1952 over 1951 is 13%, and that for 1954 over 1953 is 11%. The figure given in table II is obtained by assuming that the increase for 1953 over 1952 and the increase for 1955 over 1954 are both 12%, and from this we also

obtain the conversion factor 1 8566 "units of work" per examination That this factor is substantially accurate has been confirmed by the data we have obtained from several of the hospitals included in our analysis

The number of mass miniature radiography examinations is obtained from the Ministry of Health statistics branch Some of the remaining figures in table II have been obtained from official sources, and some are unofficial estimates by people in a position to make them As will be shown, however, their contribution to the genetically significant radiation dose is small

The total of more than 17,000,000 represents an average of one examination per person in the country every two and a half years On the basis of our samples, it appears that 7,720,000 of these annual examinations are made on the 18,500,000 people aged less than 30 This is much greater than earlier estimates, which assumed an average of only one examination per person up to the age of 30

The age and sex distributions of the hospital examinations have been determined by analysing the work of five typical hospitals—two teaching, two non-teaching, and one children's The number of examinations analysed, however, is less than 1 in 800 of the annual number of examinations for the country as a whole, and it is clear that a more complete and representative analysis is desirable This is especially true because, as will be shown later, the greater part of the dose is received during a small minority of examinations Where there was a substantial difference between the figures for the teaching and the non-teaching hospitals, the figures were weighted in favour of the non teaching hospitals On the whole, however, differences were small, as is shown in table III, which lists as percentages of all X ray diagnostic patients the numbers of all the patients (irrespective of age and sex) undergoing certain types of examination in which the doses may be high Agreement is even better when the numbers of patients under 45 years of age are extracted, as can be done for some of these hospitals

The age and sex distributions of the examinations for the N H S and non-N H S hospitals and private medical radiology have therefore been taken as the same as the mean of the figures from the five hospitals marked in table III with an asterisk, multiplied up to a total of 12,670,000 examinations The totals for all ages, but divided between the sexes and between the different types of examination, are given as percentages in table VI The distributions of the examinations for the other sources detailed in table II have been obtained and treated similarly

* Detailed statistics for these hospitals giving the age and sex distribution for all types of examination were used for the main calculations
No figures available

In view of the special circumstances, the numbers of salpingographies, radiological pelvimetries, and obstetric abdominal examinations have been obtained differently It will be seen from table III that the average percentage of salpingograms from eight hospitals is 0 082% and from this it has been assumed that the value for the country as a whole is not less than 0 05% On this basis 6330 examinations of this type are undertaken annually The information obtained about radiological pelvimetry and obstetric abdominal examinations is summarised in table IV The arithmetic means of the figures for pelvimetry and obstetric abdominal examinations are 93 and 250 per 1000 live births respectively In view of the uncertainty attaching to these figures, we assume that for the country as a whole there are not less than 60 pelvimetries and 200 obstetric abdominal examinations per 1000 live births in hospital Of the 673,651 live births in 1954, 64 1% (i e , 431,810) took place in hospital (Ministry of Health 1954) We have therefore assumed that at least 26,000 X ray pelvimetries and 86,000 obstetric abdominal X-ray examinations are made annually

Except for pelvimetries, the number of fœtal gonads irradiated has been based on the number of women in each five year age group subjected to each type of exami-

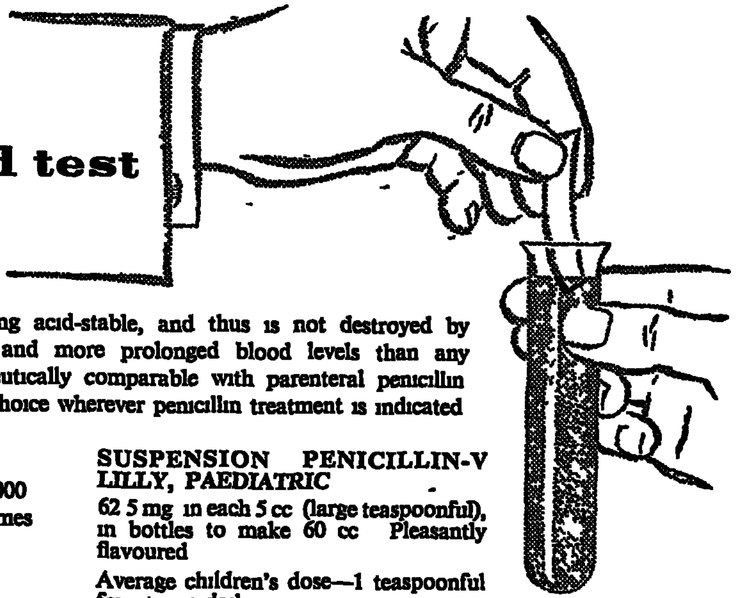
passes the acid test



Penicillin-V, Lilly, is unique in being acid-stable, and thus is not destroyed by gastric secretions It gives higher and more prolonged blood levels than any other oral penicillin, and is therapeutically comparable with parenteral penicillin Penicillin-V, Lilly, is the product of choice wherever penicillin treatment is indicated

Available as

'PULVULES' PENICILLIN-V LILLY,
125 mg In bottles of 12, 100, 500 and 1,000
Average adult dose—1 capsule four times daily, increased in severe infections

SUSPENSION PENICILLIN-V LILLY, PAEDIATRIC
62 5 mg in each 5 cc (large teaspoonful), in bottles to make 60 cc Pleasantly flavoured
Average children's dose—1 teaspoonful four times daily

suitable for all age groups

The complete answer for macrocytic anæmias

Clinical experience over a decade has established that the administration of Anahæmin constitutes the most effective form of treatment for pernicious anæmia

Anahæmin produces, with small and comparatively infrequent doses, a prompt and satisfactory erythropoiesis in patients in relapse, it ensures the maintenance of a normal erythrocyte level in patients in remission and is effective in preventing the onset of subacute combined degeneration of the cord Anahæmin has also been found to be of value in the treatment of herpes zoster and post-herpetic neuralgia The suggested dosage is 4 ml on alternate days until relief is obtained

'ANAHÆMIN'

Anahæmin is available in
1 ml ampoules, Boxes of 6 at 11/4, 25 at 43/4
2 ml ampoules, Boxes of 6 at 19/–, 25 at 74/–
Vials of 10 ml at 14/8 and 25 ml at 35/10
Basic N.H S prices

Literature and specimen packings are available to members of the Medical Profession on request

nation and on the risk of parenthood for that group. The numbers so obtained were reduced by 6% to allow for fœtal and neonatal mortality, and by 20% to allow for the well-known reluctance to radiograph a pregnant woman if the matter can wait until after the birth of the child. The number thus obtained in the case of abdominal examinations is supplemented by the number of obstetric abdominal examinations as determined above.

Doses Received by Gonads

The most comprehensive survey of radiation doses received by the gonads in diagnostic radiology is that by Stanford and Vance (1955). They emphasise the variations to be expected from case to case and also the variations between different techniques. Their figures, however, are based on the very careful techniques in use at Guy's Hospital. A smaller number of measurements made at another teaching hospital gave results on the whole similar but differing in particular examinations by a factor of more than 10. Those reported by Martin (1955) are on the whole substantially higher than those of Stanford and Vance. The Stanford and Vance dose values have been used as the basis of this work (with one or two exceptions detailed below) partly because they are conservative and partly because they are comprehensive. They do, however, only represent the technique in use at one hospital, where all reasonable steps are taken to reduce to the minimum the doses received by the gonads. Perhaps the most important of these steps are accurate coning of the X-ray beam, reducing to the minimum the number of films and screening time of each examination, and using fast films and screens where practicable. In many hospitals less care is taken over these matters. It is therefore likely that the average doses for the country are substantially higher than those of Stanford and Vance.

The doses received in pelvimetry and salpingography have been assessed separately using the minimum estimates given in the literature, by Stanford (1951) and Barnett and Bewley (1955) respectively. In calculating the dose for pelvimetry a three-film technique is assumed, although many hospitals take more than three films.

Except for X-ray pelvimetry, we have not found any published report of doses of radiation received by the fœtal gonads. We have therefore assumed that, if the fœtal gonads are exposed only to scatter, the dose is the same as that to the maternal ovaries, but if they are exposed to the direct beam, the dose is the geometric mean between the dose to the maternal ovaries and the dose to the maternal skin (Stanford and Vance 1955) except in pelvimetry, where figures based on Stanford (1951) have been used.

The doses per examination that have been used are listed in table v.

Results

The results were calculated from the available data as detailed above. The genetically significant dose of radiation received annually from all X-ray diagnostic sources in England and Wales is presented in table vi together with the percentage of each specific type of examination in terms of all the examinations undertaken. The annual totals are 496,355 r eg for males and 484,644 r eg for females. To compare these with the doses received from natural radiations it is necessary to convert the units from röntgens to rads. Spiers (1946), who calculated the absorption of energy in different types of tissue for X rays of different wave-lengths, gave 87 ergs per g per röntgen for muscle subjected to X rays of diagnostic quality. If this figure applies to gonad tissue, the two totals given above become 432,000 and 422,000 respectively when expressed in terms of rads, the total for both sexes being 854,000 rad equivalent-genetic (rad eg).

The annual doses of natural radiation calculated from the same vital statistics amount to 2,186,800 and 1,722,150 rad-eg for males and females respectively, the total for both sexes being 3,908,950 rad eg. Thus the contribution from X-ray diagnostic radiology represents an increase of 22% over the dose due to natural radiation. The data, however, were selected with a view to estimating the minimum contribution from diagnostic radiology; therefore the actual value may be several times greater than this.

Discussion

Previous estimates of the genetically significant dose of X rays from diagnostic radiology have been based on a number of examinations per annum considerably below the actual number. Stanford et al. (1952) and Stanford and Vance (1955) assume that each person undergoes one such examination up to the age of 30. Farmer (1955) calculates from two hospitals to the whole country by the ratio of beds. The figures given in table II are regarded as being considerably more accurate than either, although they are subject to a possible uncertainty of a small percentage.

The doses received (table v) are inevitably known with much less accuracy. Many other workers have observed higher doses than those used here (Osborn 1951, 1952, and unpublished observations, Macgregor and Oliver 1952, Bercy et al. 1955, Martin and Williams 1946). The doses cited by Martin (1955) are the only other comprehensive data. If these are used throughout, the genetically significant radiation due to diagnostic radiology rises from 22% to 36% of natural radiation. Further, as Stanford and Vance (1955) point out, small inaccuracies of setting up can cause great differences in the dose received by the gonads. They cite that, if for a male patient undergoing intravenous pyelography the alignment of the bladder film is incorrect and the testes are exposed to the direct beam, the dose received in the examination is increased by a factor of 25. Table vi shows that, if such an error were general, this single alteration would increase the figure of 22% to 30%.

No allowance has been made for cases where films are unsatisfactory and are repeated, or where trial or additional films are taken in addition to the normal ones for the particular examination.

The results presented here are not intended to be an accurate estimate of the genetically significant radiation dose being received from X-ray diagnostic radiology at present; insufficient data are available for this. They are intended to indicate a probable lower limit to this quantity. The actual amount being received annually at present is likely to be greater, but whether by a factor of 2, or 5, or even 10, we cannot yet say. *It is not a constant value*, for the number of diagnostic examinations in N.H.S. hospitals is apparently increasing by about

THE LANCET

LONDON SATURDAY, JUNE 16, 1956

Pain in Peptic Ulcer

THE cause of pain in peptic ulcer is probably complex. Two possible factors have received particular attention—namely acidity and motility. There is evidence to support both the "acidity" and "motility" schools of thought, just as there is evidence contrary to both. In favour of acid as the cause of pain, PALMER,[1] using a fairly high concentration of HCl found a correlation between the introduction of acid into the stomach and the onset of pain. The results of BONNEY and PICKERING[2] and others led them to the same conclusion. Against this hypothesis are the many observations showing a complete dissociation between pain and the acidity of the gastric contents.[3–5] Among the supporters of the motility school were HURST[6] and HARDT,[7] who noted pain associated with gastric contractions in the absence of free acid, and some recent work is in agreement with this conclusion.[8] When a large number of admirable observers are sharply divided into two camps, it is certainly necessary to reconsider the whole question and this has been done by SMITH[9] in a series of careful observations. He finds that there is much to be said for both sides—as well as much against them. He introduced acid and alkali into the stomach of patients with peptic ulcer, and simultaneously recorded gastric motility by means of a balloon-kymograph technique. His results make it clear that the pain of peptic ulceration cannot be satisfactorily explained solely by changes in acidity of the gastric contents, nor by varying degrees of movement of the stomach or duodenum. Some patients reacted to acid by feeling pain, others did not, but felt pain when there was no free acid or when acidity was low. SMITH records that one patient felt a spasm of pain after the gastric contents had been rendered alkaline with sodium bicarbonate. Pain and gastric motility were similarly unrelated, though occasionally movement was accompanied by pain. The only possible conclusion to be drawn from this work, as from the earlier observations, is that acidity and motility sometimes trigger pain, but they are not inevitably and causally related to it.

A third consideration is the abnormal tissue at the site of the ulcer where dead and dying cells, together with living ones, lie in inflamed and œdematous tissue. Since pain is more easily produced in an inflamed area than in a normal one, inflammation must clearly be taken into account. KINSELLA[5] held that, in logical order, inflammation was the primary cause of pain, the motor disturbance the secondary cause, and the acid the tertiary cause. Histamine was one of the first inflammation-producing substances whose action was analysed by LEWIS in his celebrated work on the triple response in skin. It is perhaps less well known that viscera also give a triple response—i.e., local œdema and wealing and, at a short distance from the site of injury, vasodilatation of arterioles via an axon reflex. The triple response follows local tissue injury and the liberation of histamine from the injured cells; it also follows the local appearance of endogenous histamine liberators, or the injection of exogenous ones, such as the lecithinase of bee-stings. But histamine is not the only substance causing inflammation and œdema. Hyaluronic acid is produced by connective tissue, and the enzyme hyaluronidase is also present in tissues in a bound form.[10] Hyaluronidase is in all probability liberated as the result of injury, and it can then convert the hyaluronic acid from its normal gel-like consistence to a more fluid sol-like state which permits the easy spread of substances in solution. This action may be demonstrated by the use of dyes.[11] Thus, where there is tissue injury there will be vasodilatation and a breakdown of tissue barriers. The resulting increase in the permeability of blood-vessel walls enables dissolved substances to spread and affect a wider area. Certain polypeptides also induce vasodilatation and probably do so in the normal organism[12] being formed from plasma-proteins by the action of enzymes released in the course of cellular activity. One such polypeptide is bradykinin. Inflammation does not of itself cause pain as was demonstrated in the stomach of Tom by WOLF and WOLFF,[13] and in skin by EMMELIN and FELDBERG,[14] who showed that nettle-stings contain histamine and acetylcholine. Injected into the skin histamine by itself causes itching and inflammation but no pain but a combination of histamine and acetylcholine causes the itching and pain characteristic of nettle-stings. In this connection, bradykinin is of particular interest because it may be a mediator of pathological pain, thus it, or a substance with similar chemical and physical properties, can be shown to have parallel effects in producing pain and vasodilatation when applied to the exposed base of a cantharidin blister in man.[15] Bradykinin is by no means the only polypeptide with such properties, in fact there is good ground for believing that in this category there are a large number of polypeptides formed by the proteolytic digestion of tissue or plasma-proteins.

In the stomach at the site of an ulcer cells have been disrupted and have liberated their enzymes and cell proteins, and exuded blood-serum is also present. These are the conditions necessary for the formation of a variety of polypeptides and for the release of histamine—all of which are liable to cause inflammation, œdema, and pain. In normal circumstances the small amounts of these substances formed would be confined in their proper channels, but where normal tissue barriers have broken down, as by the action of hyaluronidase, they may spread irregularly. Further, any stimulus causing vagal activity (in the absence of diluting food) will result in gastric movements which

12% each year. Some very fragmentary available evidence suggests, however, that the genetically significant radiation dose has not been increasing at such a high rate very long. The great improvement in film and screen speeds in the last twenty-five years has reduced the doses necessary to produce an acceptable result and has tended to compensate for the greatly increased number of examinations. In fact, it appears that thirty years ago the genetically significant radiation dose from diagnostic radiology was not very different from what it is today, within a factor of about 2. The consumption of films was then at about 20% of the present level, but the introduction of intensifying screens and the increase in film speed have reduced the average exposure to 20% or less. It is to be hoped that technical developments, such as image intensification, will bring about a further reduction in dose, thus enabling the increasing number of examinations to be made without adding to the genetically significant dose.

Table VI shows that many of the common types of examination (e.g., of limbs, teeth, and chest) contribute altogether a very small proportion of the total genetically significant radiation dose. A few other examinations (e.g., of hip and lumbar spine pyelograms, and pelvimetry) amount to only about 7% of the total number of examinations yet contribute nearly three-quarters of the total radiation. It is clear that, if it is desirable to reduce the genetically significant radiation dose from diagnostic radiology, it is this latter group of examinations that should receive first consideration. The proportion of the total dose received by fœtal gonads is particularly noteworthy.

† Percentage of all diagnostic X ray examinations in England and Wales.

‡ Percentage of all genetically significant radiation arising from diagnostic radiology in England and Wales.

Negligible dose.

It is to be hoped that a fuller investigation of techniques, doses delivered to the gonads, and radiology department statistics will enable a reasonably accurate estimate of the genetically significant radiation dose from diagnostic radiology to be made.

Conclusion

The amount of genetically significant radiation dose from diagnostic radiology is not negligible, amounting to at least 22% of that from natural radiation sources, and possibly much more than this. Whether this constitutes an appreciable genetic hazard to the population as a whole is not for us to say, but the wording of the latest recommendation by the International Commission on Radiological Protection suggests that this is not impossible.

Summary

An analysis has been made of the number of X ray diagnostic examinations performed per annum in England and Wales, and a subdivision obtained from five selected hospitals into type of examination and into age and sex of the patients examined.

In addition, an assessment has been made of the minimum dose received by the gonads in each type of examination, and the probability of reproduction as a function of age.

The results show that it is unlikely that the genetically significant radiation dose received by the population of England and Wales from X-ray diagnostic radiology amounts to less than 22% of that received from natural sources, and it may well be several times greater than this figure.

Most of this radiation is received in a few types of examination undergone by relatively few patients, and by fœtal gonads in examinations during pregnancy.

The work described here was originally undertaken for the Medical Research Council's Committee on the Medical Aspects of Nuclear Radiation, under the chairmanship of Sir Harold Himsworth. We are greatly indebted to Dr T. C. Carter for guidance on its genetic aspects and to Prof. A. Bradford Hill for helpful comment on its statistical aspects. Many other people, far too numerous to name, have provided invaluable data, especially the radiologists, radiographers, physicists, and records officers of the hospitals studied and the appropriate medical and statistical officers of various Ministries and other organisations, and we are most grateful for all the trouble they have taken.

may stir and distribute the locally accumulated breakdown products till enough sensory nerve-endings are stimulated to give a sensation of pain The gastric acid, produced by vagal activity, may reach sensitive areas and add to the pain Pepsin may attack the acellular protective coating of the ulcer base Histamine will certainly be present where there is injured tissue, and whether vagal activity will add more histamine is a moot point Acetylcholine will also be liberated at the vagal nerve-endings Whether any or all of these factors do give rise to a sensation of pain will depend on the temperament of the individual, on the conformation of the ulcer, and on other variables such as blood-pressure and blood-flow at a given moment The elimination of any one pain factor may tip the balance in the patient's favour Anticholinergic drugs, for instance, are useful because they reduce gastric movements and secretions, but they have to be given in doses which produce some general effects

The intermittency of pain in peptic ulcer is no more or less mysterious than its intermittency in any inflamed raw area, or in toothache Nor is it a peculiarity of peptic-ulcer pain that it is relieved by rest and relaxation, which reduce to a minimum the reflex stimulation of motor and secretory nerves Whether pain is or is not felt must, surely, depend on whether the many factors involved do, at a given moment, sum to a stimulus great enough to induce a sensation of pain

Cancer of the Colon

Black et al [1] have lately criticised the grounds for the assumption that five, ten, or even fifteen years' survival after treatment for cancer is in fact the result of treatment Their arguments concerning cancer of the breast add weight to this view [2], and McKinnon [3] has also pointed to the apparent failure of earlier treatment to reduce mortality from breast cancer Fortunately the doubts which these observations raise need not affect surgical judgment so far as cancer of the colon is concerned, since a lesion at this site must be removed if only to relieve diarrhœa, anæmia, and obstruction—though the surgeon naturally hopes that he is also improving the patient's chances of avoiding a recurrence Shallow et al,[4] in following 750 patients after excision of growth from the large bowel, discovered a significant decline in the incidence of recurrence or metastasis after the third year It cannot, however, be concluded that those who survive longer have surgery to thank for this, they may have had a tumour with that type of life-history

Nevertheless, surgeons continue to remove what they can when they can, and in the colon endeavour turns to dealing with recurrences The large bowel must be considered in its entirety when treating cancer discovered at one particular site, for the colon seems liable to malignant change in more than one place in the same patient Of the patients studied by Shallow et al, 42 had two separate primary lesions, and in 2 the second lesion arose after resection Ginzburg and Dreiling [5] describe 25 such patients, in 1 of whom there were three and in another four primary lesions Most of the additional lesions developed after the first one had been discovered the interval varying from one to twenty-three years Ginzburg and Dreiling pertinently observe that when another growth appears within a year it may well have been present but not noticed at the first operation Beal and Cornell [6] found 10 patients, with two simultaneous lesions in a series of 140 resections, recurrence developed at the suture line in 21 and was commonest after sigmoid resection—but this was also the commonest primary site (81 cases)

There is cogency in Cole's contention that exfoliated malignant cells may provide seedlings which grow in the suture line and thus give rise to these recurrences, and it is proper to follow his technique of occluding the bowel with tapes above and below the growth in order to avoid contamination of the proximal and distal areas destined for anastomosis [7] But it is important not to lose sight of the fact that the development of a growth in the colon may indicate a precancerous state throughout the large bowel Over thirty years ago, Dukes [8] gave evidence of this by drawing attention to adenomas Swinton and Warren [9] have found that, in 14% of 827 patients with large-bowel-growth, the lesion was proved histologically to have started in an adenomatous polyp, and 35% of their patients had multiple polyps 22% of Beal and Cornell's series were thus affected In 100 patients treated for polyps, van Buskirk [10] found adenomas to be multiple in 35 Fortunately they are usually within range of the sigmoidoscope, and this was so with 78% of van Buskirk's patients and with 70% of the polyps seen by Swinton and Warren 71 of van Buskirk's patients were examined after their original treatment and 12 were found to have new or recurrent polyps Ravdin [11] believes that nearly all multiple primary lesions are grafted on adenomatous polyps, and the incidence he cites of 75% of large-bowel cancer lying within 26 cm of the anus coincides with the distribution of adenomas But he also indicts inflammatory polyps arising in ulcerative colitis this overlooks the fact that polyps in this disease are rarely *adenomatous* indeed there is no proof yet that this condition, more properly termed pseudopolyposis to avoid confusion leads to carcinoma in ulcerative colitis, though the adenomatous polyp, when it occurs, doubtless can

These facts must be weighed in treatment Careful examination of the large gut is essential when a colonic or rectal cancer is excised, since another growth may lurk elsewhere unsuspected After resection, patients should be seen at regular intervals and the whole bowel must be investigated when suspicious symptoms start anew Ginzburg and Dreiling [5] were able to undertake further resection for 23 of their patients with subsequent primary lesions For adenomas alone the position is difficult, beyond the sigmoidoscope they are not easy to

ANTENATAL CARE

A Subject for Discussion

A CONCERTED effort against toxæmia of pregnancy is proposed by the Ministry of Health As a first step the Ministry has invited the chairmen of boards of governors, and of hospital management committees which control a substantial number of maternity beds, to convene local conferences At these, it is hoped, representatives of all the groups concerned with midwifery under the National Health Service will discuss a memorandum produced by the Standing Maternity and Midwifery Advisory Committee

This memorandum points out that, besides being the principal cause of avoidable maternal death in this country, toxæmia of pregnancy is also a major cause of stillbirth and neonatal death—nowadays often grouped together as "perinatal mortality" In the past six years the perinatal mortality for the whole country has remained stationary Many deaths could be prevented by early detection and treatment of toxæmia

> "In Aberdeen, Baird and his co workers, in Australia, the practice of the *Women's Hospital, Crown Street, Sydney*, described by Hamlin, and in New Zealand, Dawson, have shown that by more strict attention to antenatal care a significant lowering of the incidence of eclampsia and over 50% reduction in perinatal mortality rate can be obtained All attribute their success to prompt detection of toxæmia through strict attention to antenatal care followed by early admission to *hospital* and good sedation in severe pre eclampsia This early recognition of toxæmia depends upon a routine designed to detect the smallest deviation from the normal, for example, a rising blood pressure (usually a diastolic pressure of over 90 mm of mercury) slight œdema or unduly rapid gain in weight Albuminuria is considered a late sign indicating a serious risk of antepartum hæmorrhage The danger of intra uterine death of the fœtus is said to be in direct proportion to the height of the blood-pressure and it is especially great when the systolic pressure remains at 160 mm of mercury or more"

Under the maternity medical services the doctor must provide all necessary antenatal care including an examination on booking and at 36 weeks But in cases of toxæmia causing stillbirth or neonatal death, pregnancy is usually concluded before 36 weeks The reference to the 36th week may well have *obscured the importance* of a medical examination at 30–32 weeks and careful intermediate examination thereafter

The *supervision a mother* is to receive should be mapped out when the primary booking is made, and, if more than one agency is involved, it should be clear how responsibility is to be shared

> "Any evidence of malnutrition, renal disease, heart disease, pulmonary tuberculosis, or other serious illness in the past or any complications in a previous pregnancy are reasons for seeking a hospital booking It is desirable where practical that all primiparæ over the age of 30, all multiparæ over the age of 40, mothers having their fourth or more confinement and those with multiple pregnancies as well as all cases of social need should have their babies in hospital"

An X-ray examination of the chest is always advisable, and arrangements should be made for a thorough dental examination and early treatment The patient's basal blood pressure should be established during the early months of pregnancy and *her weight noted* The urine should be tested, including a catheter specimen if there is a suspicion of albuminuria Blood should be taken for examination

> "At 30–32 weeks multiple pregnancies and some obstetric abnormalities will be detectable Special attention should be paid at this stage to *the blood pressure* and any slight rise, abnormal weight gain or other sign of toxæmia should lead to frequent and regular observations in order that treatment may be provided more promptly than has been customary in the past The urine should of course be tested and albuminuria if it occurs and is not related to other known disease, should be regarded as a late sign of toxæmia to be promptly and seriously treated"

The midwife should see her patient monthly until the 28th week, fortnightly until the 34th and 36th week, and then weekly Free interchange of information between midwife and doctor should always be arranged as part of the plan for antenatal care made at the time of booking

Blood examination is needed to estimate the mother's hæmoglobin (or even for a full blood count) at booking and again at *30–32* weeks, to establish the mother's blood-group, and to establish whether or not she is rhesus negative "Tests for antibodies will be necessary later in pregnancy in rhesus negative women, and all women with antibodies should be confined in special centres with facilities for prompt exchange transfusions i e, *within eight hours of birth, if the baby requires it*" Blood tests for venereal disease are also required

Once early toxæmia and other abnormalities have been *recognised, there are* three essentials for a good service (1) a constant watch on all patients, especially non attenders, (2) an adequate number of antenatal beds *so that treatment may be started* as early as possible, and (3) for the multipara a good home help service

Medicine and the Law

Continued Detention in Institution Questioned

AT Leicester Assizes recently a man aged 26 was charged with carnal knowledge of a girl of 19 stated to be a mental defective [1] With another girl she had absconded from the institution to which she had been committed The man had found the two girls in a state of distress in the middle of the night, and had taken them to his room, where the one girl had remained for a week At first the man pleaded not *guilty to the charge of carnal knowledge*, but later he changed his plea and was given an absolute discharge Mr Justice Stable expressed concern at the *detention of the girl, and said that he would write to the* Home Secretary

It appears that in 1953 the girl was charged with *stealing 13s, was dealt with under the* Mental Deficiency Acts, and was committed to an institution At one stage she seems to have been certified as feeble minded—i e, *as a person whose mental deficiency*, though it did not amount to idiocy or imbecility, made her need care, supervision, and control From the press reports it is not clear whether she was so certified before the charge of theft or as a result of it at all events, she was later certified as a moral defective—i e, as a person whose mental deficiency is coupled with strongly vicious or criminal propensities In 1955 the order for her detention was extended for another five years, which is the normal period of extension when an order is renewed after being in force for two successive years

At the recent trial Mr Justice Stable questioned the girl about the circumstances in which this extension was ordered She told the judge that she was not interviewed at the time, nor consulted about staying another five years The judge then questioned the medical superintendent, who said that *the girl's account* was incorrect When an order was about to lapse, he said, the patient was interviewed by two special visiting magistrates accompanied by an *independent* adviser, the patient had every opportunity to make representations, and her parents or guardians could be present

Mr Justice Stable said that, having seen the girl and having had an opportunity to form an opinion about her intellectual capacity, he thought it a case which required careful revision "If she had been sentenced to borstal demonstrate, even using evacuation barium studies and air contrast 49% of those seen by van Buskirk[10] were impalpable, and at laparotomy only a large polyp can be felt with ease through the bowel wall Coloscopy, using a sigmoidoscope passed into a well-prepared bowel opened at laparotomy, has been suggested, but few would care to undertake it Since most adenomas lie, however, within the rectum or close by, sigmoidoscopy is perhaps the most valuable investigation and one which Castro et al[12] feel should be a routine whenever possible, in practical terms, the sigmoidoscope can be passed at all anal or rectal examinations Because there may be adenomas at a higher level in association with a colonic growth, Ravdin[11] recommends that colectomy should be as wide as possible compatible with preserving the major blood-supply to the remaining colon, and Lillehei and Wangensteen[13] advise total or subtotal colectomy, having operated thus for polyps or carcinoma on 73 patients with a mortality of 5 5%

Exploring Leucocyte Reserves

When a patient has a pyogenic infection or sustains an injury, there is a prompt and considerable increase in the number of granulocytes in the circulating blood Where do these granulocytes come from, how quickly can they be replaced, how big is the reserve and where is it, what is the life span of the granulocytes ? These questions are not easy to answer Yoffey[14] calculated for guineapigs that the reserve of myeloid cells in the bone-marrow was about 100 times the number of cells in the circulating blood, and he noted that 75% of the cells were segmented or band forms, ready or almost ready for discharge into the circulation Kline and Cliffton[15] estimated the average life-span of the human leucocyte at 13 2 days, a much longer life-span than had been thought likely from the results of animal experiments Osgood et al[16] labelled leucocytes with radioactive ^{32}P incorporated in the desoxyribonucleic acid (D N A) of the nuclei, and they found the life-span of granulocytes in chronic myeloid leukæmia was about 3 days, and of lymphocytes in chronic lymphatic leukæmia about 30 days Bierman et al,[17] in cross-circulation experiments in man, calculated that about 30,000 leucocytes per c mm per day left the circulation, which works out to the huge total of about 1 5 × 10^{11} daily Lawrence and his colleagues in California have approached these problems by using the technique of leucopheresis and by combining it with the marking of leucocytes with radioactive phosphorus In leucopheresis blood is withdrawn from the femoral artery of an animal the blood is centrifuged, the layer of white cells and platelets is removed, and the blood is returned to the circulation by the femoral vein, in this way it is possible to clear the leucocytes from large volumes of blood in a short time Preliminary results with leucopheresis in dogs were reported last year[18] If three blood-volumes per hour are cleared of leucocytes, the white-cell count in the peripheral blood falls to just under 20% of base level in about $1^{1}/_{2}$ hours, and this level is maintained even if the leucopheresis is continued When the removal of leucocytes is stopped, there is a pause before any new white cells appear, but after 1–2 hours the count rises rapidly for 6–8 hours until a count perhaps twice as high as the original basal count is reached, then the rate of increase slows and after 24–36 hours the count steadies at a level $2^{1}/_{2}$ to $3^{1}/_{2}$ times the original level If leucopheresis is carried out at a slower rate (say, one blood-volume cleared per hour), the white count falls to only 40–60% of the initial level and recovers quickly when the withdrawal ceases These experiments indicate that the circulating blood-volume must be cleared of leucocytes in somewhat less than one hour to exceed the rate of entry of these cells from the reserve areas, and Lawrence calculates that, for the dog, the entry of leucocytes into the blood must have been rather less than 0 8 × 10^{10} cells per hour The rate is accelerated by repeated leucopheresis, for example, in one experiment the rate of recovery after a first leucopheresis was 0 25 × 10^{10} cells entering the circulation per hour, but after a second experiment the rate was 1 7 × 10^{10} cells per hour The leucocytes that enter the blood after leucopheresis are mature types and immature cells do not appear until the 3rd or 4th day Similarly, hyperplasia of the granulocyte-forming tissue in the marrow does not show for at least 24 hours and then it increases so that many myelocytes, promyelocytes, and myeloblasts appear

This work has now been extended by Craddock et al[19] They consider that these results show that the *initial* response to loss of granulocytes is the release of mature cells from the storage areas, and the response does not depend upon growth in the marrow They found that, even in dogs who had received enough total body irradiation to cause aplasia of the marrow, the response to leucopheresis was at first similar to that of the normal animal, though the height of the leucocyte-count reached in the recovery stage is relatively low It is this reserve of mature or nearly mature granulocytes that is the source of cells for any body reaction that calls forth a leucocytosis, such as, presumably, a pyogenic infection It is therefore very important, and Craddock et al have attempted to define its site and estimate its size There are three possible sites of the "ready reserve" of leucocytes those in the blood-stream, including those sequestered in relatively stagnant parts of the vascular system, those that have migrated out into the tissues and those in the bone marrow throughout the body Craddock and his co-workers consider that replacements after leucopheresis come almost exclusively from the bone-marrow Experiments aimed at mobilising the cells in the vascular bed suggest that this source is unimportant, and leucopheresis in heavily irradiated dogs shows that a fixed agranulocytosis can occur while there are still large collections of leucocytes in the lungs and other tissues For tracing the entry into the circulation of newly formed leucocytes from the marrow, Craddock et al used the method of incorporating ^{32}P into the D N A of the leucocytes and, in view of unsatisfactory features in existing methods, they used a new technique of D N A extraction developed for them by Simmons she would have had three years' training Because she was sentenced in 1953 as a moral defective for stealing 13s, it seems amazing that she should be kept in an institution until 1960 "

The Casualty Department*

I THE WORK AND THE STAFF

T G LOWDEN

B M Oxfd, F R C S

CONSULTING SURGEON, SUNDERLAND GROUP HOSPITALS

OVER 11½ million attendances were made at casualty departments in England and Wales in 1952, and about 80% of these attendances were made at non-teaching hospitals [1] By its magnitude, the work of these departments merits far more attention than it generally gets

Whereas most parts of the hospital have had their functions developed on a clinical basis, with a tendency to more and more specialisation, the casualty department has pursued an opposite course Because the limits of its clinical work are difficult to define, it has developed on a functional basis, and it carries out minor procedures belonging to many specialties It is often a coordinating mechanism on the medical side, just as the secretary's office is a coordinating mechanism on the administrative side, and it often does work which might properly be regarded as part of the administrative machine Moreover, it is the part of the hospital most closely in contact with the public, because access to it is the most informal it is the hospital's shop window, where deficiencies are noticed by a large number of people

Unquestionably many casualty departments could be very much better than they are, and it may be useful to consider possible means of improvement and how they could be applied to the majority rather than to the few

The Work

The Patients

The patients come from many sources

1 Those with complaints which in the ordinary course of events would take them to their family doctor may come on their own initiative, because their own doctor is unavailable, because the hospital is nearer, because they think the hospital doctor is better, because they have no family doctor, or because they are away from home This type of case covers a wide field of medicine and surgery and can easily produce an unwieldy clinic

2 Patients are sent to hospital by non-medical agents, such as works foremen or the police, because it is thought that their condition needs urgent attention These cases include most minor accidents occurring in industry, in the home, and in the streets, and, in most areas, all accidents, whether major or minor

3 Patients are referred to the casualty department by general practitioners for a variety of reasons

(*a*) Because it has facilities which they believe to be better than their own, such as serum which has not become outdated, antibiotics which may not be available to them, or sterile dressings

(*b*) Because it has facilities which are not available in general practice, especially for cases requiring surgery under anæsthesia

(*c*) Because they want a second opinion, but do not regard the case as important enough to go through the formality of a consultant's outpatient clinic

(*d*) Because they think that the case needs hospital treatment urgently

(*e*) Because they require an X ray report 5–10% of all cases coming to certain casualty departments are sent for X ray examination to confirm, as a medicolegal precaution, the *absence* of bony injury

4 Other departments in the same hospital, or other hospitals may refer cases, mainly for minor surgery, or for postoperative outpatient dressings

5 Many casualty departments, because they deal with the admission and disposal of casual or urgent cases, are used also as the reception department for waiting-list and outpatient cases Some do this only outside normal office hours, but others do it at all times of the day

The Responsibilities

The department's responsibilities may be divided into those of treatment and those of disposal In highly organised and departmentalised areas disposal duties increase at the expense of treatment, because an increase in the number of special clinics increases the indications to refer casualty cases elsewhere

This particularly affects the treatment of fractures When accident services are inadequate to cope with all fractures, casualty departments may have to reduce fractures and refer them only for further reduction (if that is necessary) and rehabilitation Some are required to treat ambulant fractures and refer the rest to fracture services In a few places, where a well-organised and entirely adequate fracture service operates, the casualty department's responsibility is confined to diagnosis, except for the occasional fracture or fracture-dislocation which needs urgent release of pressure upon vessels or nerves

Some casualty departments control beds in a short-stay ward, undertake resuscitation and preoperative preparation, and hold cases for twenty-four or forty eight hours for clinical observation or for postoperative care

A highly departmentalised area tends to split up the work still further Children's hospitals, accident hospitals, " mainly general " hospitals (which are usually ex-municipal hospitals), and sometimes as many as three general hospitals in the same area, all maintain facilities for treating the same type of case Works first aid posts, pithead clinics, and clinics run by industrial and school medical officers contribute to the dissemination of effort

Up to one-fifth of all casualty cases may be suffering from acute superficial sepsis Where the department deals with fractures, the tendency is for acute sepsis to come among the responsibilities of the orthopædic or accident service Tendon injuries also, because they are often associated with fractures or injuries to the joints, are being included in the orthopædic surgeon's sphere On the other hand, many accident services are at present far from comprehensive The capacity or the situation of an accident hospital may limit its influence to less than half the community concerned It may accept only bone and joint cases, whereas burns, soft tissue, visceral, and head injuries are accommodated elsewhere

The segregation of accident cases from other types of surgical case has many disadvantages, and as strong an argument can be produced for the development of the accident service in close association with a general surgical as with an orthopædic unit Furthermore, it is possible that an accident hospital is less desirable than an accident service within a general hospital A " complete " hospital offers a better opportunity to mobilise various specialties for the treatment of multiple injuries, and an accident hospital may have to duplicate ancillary services, such as bacteriology, pathology, and blood transfusion units, which are better centralised

The Staff

The care of the casualty patients is in the hands of people with widely varying abilities, and, although nowadays there is a tendency for the department to

---

* First of three articles dealing with some of the difficulties facing casualty departments of non teaching hospitals, and outlining a scheme for a more comprehensive accident service

[1] Hospital and Specialist Services England and Wales Statistics for the Year ended Dec 31 1952 H M Stationery Office 1954

Since the response to leucopheresis comes almost exclusively from the myeloid cells, no separation of granulocytes and lymphocytes was made The results show that it is about 3 days before cells containing ^{32}P appear in the circulation, leucopheresis carried out 24 hours after the administration of ^{32}P yields cells that are unlabelled It is therefore possible to choose a time, about the 3rd day after the dose of ^{32}P, when the peripheral leucocytes still contain only negligible amounts of labelled D N A, but when the almost mature cells in the marrow have a very high activity Leucopheresis experiments at such a time show that the activity of the cells removed from the circulating blood at the first clearance is only low But when, after the lag period of 1–2 hours, the leucocyte-count begins to rise, the cells have a high specific activity and clearly most of them come from the marrow pool of labelled granulocytes

CRADDOCK et al consider that their data show that the release of leucocytes from the marrow is " geared to the utilization rate of leukocytes in the periphery ", the cells may be migrating into the tissues or being destroyed in the circulation But the marrow tissue takes time to respond by hyperplasia to demands for more leucocytes, and sudden calls are met initially from this reserve of relatively mature cells in the marrow This reserve appears to be large, " the marrow reserve," they say, " affords a huge buffer between supply by growth, which is fixed within certain limits, and demand, which may vary very widely The rate and degree of replenishment of the peripheral blood with leukocytes under conditions of increased need is initially geared to the marrow reserves and not to the rate of growth of myeloid tissue " These results are of much interest The type of response described by the Californian workers applies to loss of leucocytes only and it remains to be confirmed that the response to inflammation or infection is indeed similar But in the meantime the idea of a large marrow reserve of mature neutrophil granulocytes, mentioned by YOFFEY, must be taken into account when explaining leucocyte reactions The idea may explain, for instance, why in acute agranulocytosis the bone-marrow is found so often to be almost entirely denuded of myeloid cells at the time of clinical onset, the answer may well be that the marrow was damaged some time before and the clinical agranulocytosis appears when the reserve pool is exhausted Compared with what we know about the erythrocyte, our knowledge of the quantitative physiology of leucocytes is indeed small, but researches like those we have described are now yielding results

Annotations

THE E E G AND THE CLASSIFICATION OF EPILEPSY

IN the past decade or so the electroencephalographic findings in epilepsy have illustrated how advances in diagnostic technique may raise problems in clinical classification For instance, a characteristic E E G pattern —bilaterally synchronous 3 per second wave and spike —is so common in petit mal that the terms " petit mal " and " wave and-spike dysrhythmia " are at times used interchangeably There are difficulties in such a usage The correlation between cases diagnosed clinically as petit mal and the occurrence of wave and-spike patterns is as high as 80% in some large series But when the position is viewed from the other direction, and all wave and spike records are screened for the type of clinical attack they show, the figures are much less convincing. Moreover, the 3-per-second wave and-spike may show slow or fast variants, though the general pattern is maintained If only " classical 3 per second wave and spike " is accepted in E E G diagnosis, then some cases which would be generally regarded clinically as petit mal will be excluded, on the other hand, if variants are included, then many cases clinically quite unlike petit mal will be found, especially in the group of akinetic and myoclonic epilepsies Indeed, in these two groups, the E E G findings, and often the response to the newer petit-mal anticonvulsants, have suggested that they are linked with petit mal, and the term " petit mal triad " has been coined to cover the three Even with a broader equation of petit mal triad and wave and spike pattern, however, a difficulty may still arise clinically in distinguishing true petit mal from psychomotor or temporal-lobe epilepsy, when the latter consists only in momentary clouding of consciousness with vasomotor change and brief automatism

There are thus arguments from both the clinical and E E G aspect against equating petit mal and wave and-spike dysrhythmia, while recognising a close link which is valuable in diagnosis The difficulty is partly one of nomenclature and may be largely overcome, as Symonds[1] suggests, by the introduction of new terms which are based on recent E E G knowledge and are untrammelled by past clinical associations

The problem has recently been considered by Clark and Knott,[2] who found that of 178 patients with wave and spike patterns only 16% had attacks which were entirely of the petit mal triad, and though 70% had these in addition to other types of attack, 30% had no attacks which could be so classified These findings illustrate clearly both the diagnostically useful correlation between the clinical and the electrical evidence, and the difficulties of considering the two as synonymous Clark and Knott also found, as have others, that classical 3 per second wave and-spike, though not its variants, is closely associated with idiopathic epilepsy, and this is in some ways the most reliable implication of the E E G evidence

The logical development in the classification of epilepsies is to group them according to the site of origin of the epileptic discharge This was envisaged by Hughlings Jackson in his conception of the aura, or " local sign," of an attack as demonstrating its site of origin The E E G, and its extension to electrocorticography and recording from the depth of the brain, is an important aid in this development, since it may localise accurately the site of electrical discharge Already, evidence suggests that the initial disturbance in petit mal may be in the thalamus, and in this sense we may soon be able to recognise with some confidence cortical, thalamic, and even hypothalamic epilepsies But the growing knowledge of the complexity and profusion of connections between cortex and subcortical structures certainly does not suggest that the initial discharge or its clinical manifestations will remain so conveniently localised

SPLENECTOMY FOR BACTERIAL ENDOCARDITIS

TEN years of antibiotics have so improved the outlook in bacterial endocarditis that two thirds of those affected may now be expected to recover In a disease which in the past was almost always fatal, this is a great advance, but there is still a challenge in the fact that 1 patient in 3 will not survive In many ultimately fatal cases, the enlist the help of increasingly senior people, there are many patients who do not see a doctor on first attendance, and some who do not see a doctor at all.

---

Local Practitioners

In some clinics local practitioners attend at prearranged times, and see cases which are referred to them by the nursing staff, and some small towns staff the local casualty department with a rota of the local practitioners. The system has evolved in response to local demands, and often works very well.

The General Medical Services Committee of the B.M.A.[2] has recommended that help for the casualty department from local practitioners should be encouraged, because of the shortage of junior hospital officers, and according to a report of the Ministry of Health[1] general practitioners already attend to approximately 8% of casualty patients. I think that this figure includes many who do not see a doctor at all.

Residents' Rota

A second common method of supervision in small hospitals is for house-surgeons and other residents to submit to a rota of duty in the casualty department, each taking his turn to deal with the daily clinic and to attend to new patients as they arrive. The work is frequently put upon that house surgeon who is on inpatient emergency duty, and this means that calls to casualty fall on the busiest resident who is least able to attend to them promptly. This is sometimes only a nominal arrangement, and the department is actually covered by extemporisations made amongst the residents themselves—residents of all specialties "rallying round" a young colleague who is under heavy pressure of work. I believe that many administrators are quite unaware of the extent to which this system depends on the spirit of fellowship which inspires residents to help one another out of difficulties.

Casualty Officers

Most general hospitals of 200 beds or over have an establishment for a casualty officer, but frequently the appointment is shared with another department, such as orthopædics, E.N.T., eyes, skins, or anæsthetics. This is seldom attractive to the young medical graduate, and is often the last vacancy to be filled from a batch of applicants.

It should also be admitted, in spite of what has been said about the cooperation between the residents, that in some hospitals relief duties in the casualty department are irksome to residents busy with inpatient work, and are a cause of friction where the morale of the staff is low.

A few larger non-teaching hospitals have more than one casualty officer, usually a registrar or senior house officer, and a recently qualified junior house-surgeon. Here again, as in many features of this department, custom plays a greater part than reason. Some hospitals with an establishment for two casualty officers do no more work than others with one. Some have more than two, allowing generous off-duty periods for study.

Senior Casualty Officers

A recently established grade is the senior casualty officer, with the same pay and status as a senior hospital medical officer. His appointment does not exceed four years. The grade is designed to establish a more responsible and experienced type of doctor in the department, and to give the opportunity for an improvement in the standard of clinical work. It is being filled at present mainly by senior registrars who have exhausted their inpatient appointments without an early prospect of promotion, and who, for the most part, have their eyes turned elsewhere. Anyone intending to specialise in major surgery is unlikely to regard four years in a casualty department as other than a period of marking time, unless opportunities are created in the future for him to utilise the experience he has gained. With the exception of two or three teaching hospitals, where full-time consultants have been appointed, opportunities for advancement within the casualty departments do not exist.

Consultants

The day-to-day participation of consultants in the activities of the casualty department is uncommon. In some hospitals a regular weekly or twice-weekly clinic is held by a consultant surgeon in or close to the department, but the type of case he sees may be selected according to his particular interests—in septic hands perhaps, or fractures—rather than according to the severity or length of the illness.

A casualty patient may therefore receive attention at the hands of any grade in the hospital service, from senior nurse to consultant surgeon. The clinical severity of the condition is not the only consideration which determines the quality of attention. The status of the medical attendant tends to rise with the amount of work at the clinic, but even this is not always the governing factor, and established custom plays a great part.

Parliament

The Laissez-faire Loaf

IN the House of Lords, on June 7, Lord HANKEY, who rose to ask the Government for information about the bread of the nation, pointed out that in approving the report of the Cohen Panel the Government had overruled their own experts. The result, he said, was not a health loaf, but a whitewashed political loaf, denatured, shorn of its bran, with its store of Nature's best replaced by three synthetic products of a chemical factory. It was a loaf that could not be produced without improvers and bleachers. Since the agene fiasco he believed that Parliament should not sanction a bread that could not be made without an improver. Four improvers were now permitted—chlorine dioxide, potassium bromate, ascorbic acid, and an aeration process. The last was less suspect than the three chemical improvers. For the most part the millers had adopted chlorine dioxide. This choice made Lord Hankey uneasy, for chlorine dioxide was twice as powerful as agene and might therefore be twice as dangerous. In his view it was not free from suspicion. It was known to destroy vitamins E and B_1 and the essential fatty acids, and it had lately been suggested that lack of this beneficial trinity, due partly to low extraction of flour and partly to the use of improvers, was influencing the growing prevalence of diseases such as coronary thrombosis, lung cancer, and leukæmia. The protection against ill health which Nature provided in the grain was being whittled away to meet a carefully fostered craving for white bread. The synthetic substances that it was proposed to add to the 70% bread would not make good the loss, even if the industries concerned could be relied on to supply them. He urged the Government to accept the advice of their own experts and stand firm on 80%-extraction bread, but this time without chemical improvers.

"Bread and flour of high extraction without added oxidising agents, and margarine and shortening made with less hardening of fats, would be important factors in decreasing some very serious diseases of civilisation."

Lord DOUGLAS of BARLOCH said that a persistent endeavour was being made to pretend that starchy flour was equal to or better than wholemeal. The last experiment used in support of this thesis was conducted in two German orphanages. Yet in fact it proved nothing except that if you took a number of undernourished children and fed them with anything they would make infection is subdued but death follows from the mechanical effects of the damaged valve , in others, the infection is never controlled in spite of appropriate antibiotic therapy In such cases it has been suggested that the infection is maintained by the presence of septic infarcts in the spleen, and from time to time splenectomy has been advocated

In pre-antibiotic days, Polowe[1] reviewed 15 cases in which splenectomy failed to prevent a fatal outcome More recently, Fellinger and Weissel[2] in Germany and Giraud and his colleagues[3] in France have tried the operation with antibiotic cover, but their results have been equivocal In America Lingeman et al,[4] from Indianapolis, report 3 cases in which operation appeared to be the deciding move that achieved a cure All 3 patients had had episodes of splenic pain, and infected infarcts were found, although the spleens had not been palpable before operation

There is no evidence from the few cases that have been reported to suggest that splenectomy should be widely undertaken in the treatment of bacterial endocarditis , but the possibility that splenectomy may help should not be dismissed out of hand

PELVIC ARTERIOGRAPHY

ALTHOUGH cerebral arteriography is now a well-established means of localising intracranial lesions only recently has the use of angiography been extended to other sites in the body , and there is now much interest in its possible value in the diagnosis of pelvic disease The first accounts were of pelvic arteriograms after translumbar puncture of the aorta,[5 6] and though Hartnett[7] *described the operation as* a "*simple procedure*," no British workers seem to have accepted his reassurance In 1952 Sutton,[8] in this country, and Borell et al ,[9] in Sweden, showed that pelvic angiograms could be obtained by percutaneous retrograde injection of the femoral and iliac arteries , the Swedish workers have continued to use this method, and an excellent monograph by Fernstrom[10] is now available, from which the value of the technique may be assessed

The femoral artery is punctured just below the groin and a 'Polythene' catheter is introduced up the external iliac artery to a point near the aortic bifurcation (Bilateral filling is important to get the greatest diagnostic help) A pressure syringe is used to inject 40 to 50 *ml of opaque* solution within three seconds Using this technique, 700 injections have been given to 448 patients There have been no complications worse than urticaria, nausea and vomiting From the many beautiful illustrations in Fernstrom's monograph, it is easy to appreciate the disturbances of the normal vascular pattern typical of uterine fibroids, as distinct from ovarian cysts, to pick out tubal pregnancies, and often to define the site of the placenta Yet it is doubtful whether this technique, which has yielded much valuable experimental evidence has a place in everyday practice Except in placental localisation, the information it gives will not commonly be required and in the definition of the placental site soft tissue radiography, as developed by Reid[11] and Whitehead[12] gives comparable results and avoids what must sometimes be a trying experience for the patient

SALIVARY CYLINDROMA

THE term "cylindroma" was first used by Billroth in 1859 to describe a tumour of peculiar histological pattern, in which alternating cylinders of cells and hyaline material are arranged round a central cavity which may contain mucus Gradually the term has come to be applied to salivary, and sometimes to bronchial, adenomas of this pattern In salivary tumours the name has been extended to apply also to adenomas composed of small dark cells resembling basal cells, with few mitoses, arranged round cystic cavities, sometimes in one or two layers The hyaline material and mucus are usually Schiff-positive

The present-day emergence of "cylindroma" from the welter of names describing salivary tumours has been explained by Harrison[1] in a recent Hunterian lecture on ectopic mixed salivary tumours In a study of 82 of these growths treated over sixteen years, he found that whereas two-thirds of the 29 patients with "mixed" adenomas were alive and well up to fourteen years after treatment of the primary growth, those with a cylindromatous tumour showed a disturbingly high rate of recurrences and mortality 50% of 46 patients were dead within eight years, and another 25% had frank local recurrence Only 8 patients were alive and well and only 4 of these for five years or more In 9 cases there was metastasis to cervical lymph-nodes and in 6 metastasis to viscera and skeleton

The grave prognosis of the cylindromatous type of tumour prompted a detailed study Harrison found this type was more common in ectopic sites 66% of cylindromas were outside the major salivary glands the commonest site being the hard palate , all the tumours found at the base of the tongue were cylindromas Two thirds of the tumours were in females, usually between 30 and 70 years of age Lemaître et al[2] found cylindroma most commonly in the parotid and submaxillary glands but Berdal and Mylius[3] agree with Harrison that ectopic sites are more usual The tumour can occur in any part of the anterior-foregut region and respiratory tract down to the lower bronchi It presents clinically as a slowly growing swelling, most commonly of the hard palate It may be small or involve the whole palate Ulceration is common, but it is often symptomless unless it invades the maxillary sinus, when there is pain, or the nasal cavity, when obstruction results The course is one of relentless recurrent growth, with a tendency to invasion of the skull[4] Metastases occur late and are found in the lymph-nodes, lungs,[1] bones,[3 4] brain,[1] liver,[1 5] and kidney[5]

The results of treatment are uniformly poor, whether by radium, X rays, or surgery, either singly or combined Harrison observed recurrence after treatment in two thirds of his cases up to twelve years after treatment of the primary tumour The best treatment seems to be wide radical excision of the surgically accessible tumours[1 3] Biopsy before the histological pattern is destroyed by irradiation is important,[4] so that the surgeon may be aware beforehand of the need for wide excision Radiosensitivity is low, particularly when bone is invaded.[3]

The behaviour and results of treatment of cylindroma prompt the question whether it is not in fact a histological variant of salivary carcinoma Bauer and Bauer[5] classify it as adenocarcinoma, noting the tendency to invade capsular tissues, nerve-sheaths, and lymphatics Willis,[6] emphasising the malignant potentialities of salivary adenomas, illustrates a cylindromatous *tumour* which recurred as frankly undifferentiated carcinoma after excision Both Lemaître et al[2] and Berdal and Mylius[3] point out, however that pure cylindroma should be dis-fairly rapid progress in weight and height The fundamental question to be answered was what was the effect of eating bleached and denatured bread and other flour products, not over a year, but over a life-time

Lord Douglas took exception to the use of such words as “ enrichment ” and “ fortification ” when applied to a flour that was really impoverished Nor did he agree with the Cohen Panel's view that people would necessarily get what was needed for nutrition from the rest of their diet The rest of their diet was also steadily being impoverished by processing and chemical treatments He was against compulsion, but he believed that people should be told the truth If it was desired to go on producing flour which has been bleached, it should be labelled “ Bleached with chlorine dioxide ” When people knew how their food was being impoverished they would make up their minds about what was best for them

Lord TEVIOT pointed out that large combine bakeries were buying up the smaller bakeries, where most of the wholemeal bread was made Those who stood up for the health of the people had a tremendous vested interest against them in the millers, and on top of that there was the vested interest of those who made the medicines to cure the evil which the other people had created Lord BALFOUR of BURLEIGH, as a former chairman of the Medical Research Council, regretted that the Government should disregard the opinion of their scientific advisers

Lord STAMP, returning to the effects of improvers, said that chlorine dioxide had no harmful effect on animals, and extensive experiments at the Cereals Research Station showed that of the substances important for nutrition it destroyed only vitamin E No other change was noted except some oxidation of the unsaturated fatty acids These facts were known to the M R C committee when the use of chlorine dioxide was sanctioned Prolonged storage would have much the same effect Nor was bread our only source of these substances It had been calculated that in an average mixed diet bread made from untreated flour would supply only about 20% of our intake of vitamin E Sterility, muscular dystrophy, and coronary disease had all been attributed to lack of vitamin E, but treatment of these conditions by vitamin-E medication had been disappointing Deficiency of vitamin E and unsaturated fatty acids had yet to be associated definitely with impaired health in human beings There seemed, therefore, to be no case for condemning the use of chlorine dioxide as a flour-improver on these grounds But that was not to say that it could be regarded as completely satisfactory The search must continue for a method which was above all criticism and which was acceptable to all sides

Lord SEMPILL wanted to see the establishment, under the Ministry of Health, of a counterpart of the Food and Drug Administration of the United States No new chemicals should be allowed in food processing and production before they had been adequately tested for their toxic effects

Lord HADEN-GUEST thought that previous speakers had exaggerated the effects of bread on the general health situation The physical condition of the population was better now than it had ever been He was certain that a large proportion of the people of this country would refuse to eat wholemeal bread, because they did not like it.

Earl ST ALDWYN, parliamentary secretary to the Ministry of Agriculture, said that the Government did not require the use of improvers, they did not even advise that improvers should be used, they merely refrained from preventing their use It would have been wrong to use statutory powers to rush the millers into giving up the agene process without allowing them time to make other arrangements It remained true that no-one had yet succeeded in demonstrating that flour treated with agene did any harm to human beings. Admittedly agene had been found to cause hysteria in dogs, but no such evidence had been found against any of the improvers now used Experts were not yet clear about the part which vitamin E played in the human diet But bread was by no means the only source of vitamin E, and, though flour treated with improvers had been eaten in large quantities for many years, there was plenty of evidence to show that vitamin E was present in large amounts in the blood of the inhabitants of this country No-one had yet succeeded in demonstrating that lack of this vitamin caused any known illness Fatty acids were also present in other foods Calculations made by the Ministry of Agriculture, Fisheries, and Food suggested that the amount of fatty acids in the British diet was 40% more than before the 1914–18 war There was no evidence which would justify the Government in prohibiting the use of improvers, but they would be kept under close scrutiny In reply to a question from Lord HANKEY, he said that the aeration process was in use but needed expensive machinery

Turning to the composition of flour, he pointed out that here again the Government were not requiring people to eat the whiter bread, the Government were merely refraining from denying it to them The Government were now proposing to take the subsidy off bread, and in the future bakers would be free to produce whatever bread they liked—or the consumers liked—at a free market price Regulations would be laid before Parliament under the Food and Drugs Act, 1955, requiring that all flour should contain not less vitamin B_1, nicotinic acid, and iron than was at present required to be restored to the whiter flour For technical reasons the minimum extraction-rate of 80% for subsidised flour was difficult to enforce The keen demand for the whitest available National bread had led traders to take advantage of the difficulties of enforcement The result was that in practice the flour being used for subsidised National bread contained less of the token nutrients than the flour used for unsubsidised bread

The Government had been chided for not accepting the advice of their own experts They were not so much rejecting the advice as being confronted with conflicting advice Into the balance between the two scientific points of view the responsible Ministers had thrown two other considerations which were not the concern of scientists as such First, there was the political view that by and large it was undesirable to require people to eat one thing when they obviously preferred another Secondly, there was the administrative view of the difficulty of enforcing regulations prescribing a minimum extraction-rate for flour The Government would await the advice of the Food Standards Committee, who would be asked to consider whether, in addition to the requirements about the token nutrients, more extensive regulations governing the composition of flour and bread were needed to protect consumers

Crown Privilege for Documents

In the House of Lords on June 6, Viscount KILMUIR, the Lord Chancellor, made a statement on the Government's policy on Crown privilege for documents and oral evidence The problem, he said, was not a new one but had come into prominence of recent years, because, since the Crown Proceedings Act, 1947, the Crown had been liable to be sued in the same way as private persons This change had thrown into relief its privileged position with regard to the production of documents and other evidence In the course of his statement Lord Kilmuir dealt specially with medical reports and records

In the recent case of Ellis *v* the Home Office, he recalled, judicial criticism was directed at a claim for privilege for reports made by a prison doctor which might have been relevant to the claim for negligence against the Crown Here the Government had two proposals to make The first was that ordinary medical records kept by departments in respect of the health of civilian employees should not be the subject of Crown privilege In the case of medical reports and records in the Fighting Services the Government considered that privilege should still be claimed, so far as proceedings between private litigants—usually matrimonial proceedings—were concerned Service doctors owed a special duty to the commanding officer, and frank reports were essential. It was also important in the Services that a man should report readily to the medical officer, who was a doctor tinguished from "mixed" adenomas with areas of cylindromatous pattern Russell[4] considers that cylindroma merits separation as a clinical and pathological entity from salivary adenocarcinoma because of its relatively slow growth, uniform histological pattern, and the rarity and late appearance of metastases, the converse features are usual in salivary adenocarcinoma Whatever the truth about the classification or nomenclature of the cylindroma, it seems that recognition of the microscopic pattern by the pathologist is the first step in the attack on this rare but serious disease

DIFFUSING CAPACITY IN EMPHYSEMA

BECAUSE of the many difficulties involved, there have been few lengthy studies of the course of emphysema, and the one by Bates and his colleagues[5] is therefore all the more welcome They observed 59 patients with clinical evidence of emphysema for as long as five years in some cases and for three years on the average In addition to other criteria, patients were admitted to the series only if dyspnœa was present at all seasons of the year and if no cause other than respiratory disease could be found for it Patients in whom pulmonary heart disease had developed were not included Pulmonary function tests—vital capacity, functional residual capacity, mixing efficiency, maximum ventilatory volume, and diffusing capacity—were carried out initially and at intervals thereafter, so that the results could be compared with clinical progress There were 17 deaths during the observation period, 4 from non-respiratory causes and the other 13 (76% of the deaths) from pulmonary heart disease According to life tables, the expected number of deaths for the period was 4 Clinical deterioration in individual cases was reflected in the results of all the function tests with one important exception the approaching onset of pulmonary heart disease was heralded only by a fall in the diffusing capacity of the lungs

The patients were also divided into groups according to the degree of dyspnœa present, and the results of pulmonary function tests in each group were compared with those in the other groups and with the results of the same tests in a group of patients with seasonal dyspnœa and evidence only of chronic bronchitis The mean values of the function tests declined progressively from the chronic bronchitic group to the most dyspnœic emphysema group—a "poor prognosis" group—which comprised patients who died within six months of their last function test There was a considerable overlap, however, in the findings in the different groups, and the only test which clearly separated the ones at opposite ends of the scale of clinical severity (the chronic-bronchitic and the "poor prognosis" groups) was the test of diffusing capacity

The diffusing capacity of the lung may be defined as the quantity of reference gas (Bates et al used carbon monoxide) which passes per minute from the alveoli into the blood at a pressure gradient of 1 mm Hg The lack of correlation between the results of this test and those of the determinations of vital capacity, functional residual capacity, mixing efficiency, and maximum ventilatory volume is in accordance with the observations of Shepard et al[6] in patients with chronic obstructive disease of the respiratory passages To explain the discrepancy, they postulated that a fall in diffusing capacity is related mainly to impairment of the blood gas exchange surface of the lungs, whereas the results of the other tests reflect principally the degree of obstruction of the airway Diffusing capacity in emphysema can therefore be reduced by actual loss of alveoli, by diminution of the blood-supply to the alveoli which remain, or by thickening due to œdema from right ventricular failure Bronchial obstruction, however, by producing irregularity of gas distribution and thus limiting the effective area of blood gas exchange, may also reduce the diffusing capacity,[5 6] and a lessening of bronchospasm may therefore account for an improvement in the figures which was noted in one of Bates et al 's cases It has also been shown that the validity of the test is increased if it is carried out when the patient is doing sufficient exercise to ensure that the whole of the available vascular bed is brought into use[7] Bates et al are convinced that tests of diffusing capacity are an indispensable aid in the prognosis of emphysema, because, although tests of ventilatory function correlate well with the degree of dyspnœa, the reduction of the pulmonary capillary bed which precedes the onset of right ventricular failure may not be accompanied by an appreciable increase in breathlessness and can be detected only by a fall in the diffusing capacity

Further work on the value of estimating the diffusing capacity in chronic obstructive disease of the respiratory passages is clearly desirable, for if it is found that current tests, or refinements of them, are capable of detecting the onset and indicating the extent of pulmonary damage, clinical analysis of this condition will gain greatly in precision Moreover, if effective remedies for chronic bronchitis are discovered, it should be possible to predict how far they will relieve disability in the individual case

RUPTURE OF THE SPLEEN

THE spleen not uncommonly ruptures after injury to the upper abdomen, such as a motor accident in which the driver is forced against the steering wheel Spontaneous rupture is a well-known complication of diseases in which the spleen is greatly enlarged, particularly malaria, and it has been reported after infarction It is usually all too plain that some intra-abdominal catastrophe has befallen, and the diagnosis may not be difficult But delayed rupture, with signs appearing some time after the injury, is a well known diagnostic trap, and X-ray examination may help

In straight films of the normal abdomen, the spleen is visible in whole or in part, especially when the stomach and splenic flexure contain gas When the spleen is small and clearly seen on the radiograph, rupture is a very unlikely diagnosis When the spleen has ruptured its outline is either partly or wholly obliterated The fundus of the stomach may be displaced medially and the splenic flexure downwards There may be slight elevation of the left side of the diaphragm, and any associated retroperitoneal hæmorrhage or œdema may obscure the upper part of the psoas shadow on the left and the outline of the left kidney

Deaver,[8] Frimmen Dahl,[9] and O'Neil and Rousseau[10] have placed the radiological signs on record In a recent paper, Wang and Robbins[11] analysed 33 cases to determine the frequency with which these signs are found 25 showed complete and 6 partial obliteration of the splenic outline The 2 patients in which the organ looked normal had small intracapsular hæmorrhages 18 showed complete and 7 partial loss of the left renal outline, and in 6 the kidneys were displaced downwards In roughly half, the left psoas shadow was more or less obliterated, and there was displacement of the stomach or colon Rather less than a third showed fracture of the ribs, and in 3 there was widening of the dorsal paravertebral space by upward extension of retroperitoneal hæmorrhage or œdema

Prof W H WYNN, of Birmingham, died on June 11.

not of his choice but in whom he must have confidence this was especially so in the case of venereal disease Some of these considerations applied to prison doctors, who owed a special duty to the prison governor, and their reports and records should still be privileged in proceedings between private litigants

Where, however, the Crown or the doctor employed by the Crown was being sued for negligence, the Government proposed that privilege should not be claimed With regard to both proposals he added, there might be reports of a specially confidential character which ought still to be privileged The Government also proposed that, if medical documents or indeed other documents, were relevant to the defence in criminal proceedings, Crown privilege should not be claimed At present many of these documents were made available only on the more serious crimes, such as murder, manslaughter, and rape

Milk Tablets for School-children

In the House of Commons on June 6, Mr **Michael Stewart** prayed against the regulations permitting local authorities to supply milk tablets in schools if milk of the proper quality is not available at a reasonable price[1] He asked for an assurance that children who were supplied with milk tablets were not likely to suffer in nutrition, health, or in any way, and that in every important respect these milk tablets were as good as milk Had the emergence of the milk tablet over the horizon, particularly in the great cities, caused suppliers to modify their view as to the price they should charge[2] Last year about a quarter of the milk supplied to schools was supplied at a discount If we could get all milk supplied at the same discount we could save £270,000 a year—more than the Government's proposed economies in milk for nursery-school children

Mr **Horace King** agreed that by supplying milk tablets we might bring the suppliers to heel but we also faced the possibility of a dangerous setback in milk consumption by our children Sir **Charles Taylor**, who declared his interest in the milk industry, pointed out that the supply of school milk in $^1/_3$-pint bottles required a special bottling machine, the bottle probably cost as much as, if not more than, its contents

Mr **Dennis Vosper**, parliamentary secretary to the Ministry of Education, said that the regulations were necessary to ensure the continuance of school milk He gave an assurance that the milk tablets were nutritionally equal to liquid milk and that they had the approval of the Ministry of Food They were more attractive to school-children than dried milk and the cost was no greater, but little less, than that of liquid or dried milk There had been criticism of milk tablets in certain schools, but the Ministry had no positive evidence that they had been much abused

When the Minister of Education took over the supply of milk, he recalled, it was thought reasonable to expect a discount on bulk supply, as in hospitals and other institutions Local education authorities were therefore expected through normal tendering procedure to secure reasonable terms for the supply of milk Their original efforts met with organised resistance, and the Public Accounts Committee in their third report in 1955–56 recommended that all possible steps should be taken to secure that milk was supplied to schools at genuinely competitive prices That report was sent to local authorities towards the end of last year together with a letter saying that the Minister would give the authorities support in any action they thought fit to take, even to the extent of stopping the supplies of school milk He was glad to say that had not been necessary It would be wrong to think that the milk tablet was the only method employed to secure reductions in price In May, 1955, of 83 county boroughs 55 were paying the maximum retail price for milk In May, 1956 only 2 county boroughs were doing so He hoped that it might not be necessary for the local authorities to use the regulations and that the desire of the Minister and the House that supplies of liquid milk should be available to all school-children at a reasonable cost would be achieved If that did not happen it might be necessary from time to time to appeal for the use of tablets of dried milk, not in preference to liquid milk but as an adequate alternative to paying an unreasonable price The motion was by leave withdrawn

Medical Bill

In the House of Lords on June 6 Viscount **Kilmuir**, the Lord Chancellor, introduced the Medical Bill, a measure to consolidate enactments relating to medical practitioners with corrections and improvements made under the Consolidation of Enactments (Procedure) Act, 1949

QUESTION TIME

Health Visitors in Scotland

Replying to a question, Mr **James Stuart**, Secretary of State for Scotland said that staff employed on health visiting duties in Scotland at the end of 1955 were equivalent to 1160 whole time visitors, about a third not being fully qualified The Working Party on Health Visitors, in their recent report, proposed a target of 1 visitor to 4300 population, which for Scotland as a whole would be met by just under 1200 visitor

R A F Medical Officers and Flying Experience

Replying to a question, Mr **Nigel Birch**, Secretary of State for Air, said that a number of medical officers were trained to fly modern operational aircraft and served for a time as pilots They were subsequently employed in special posts at the Institute of Aviation Medicine, at certain flying stations and Command headquarters, and at the Air Ministry where their flying experience was of particular value From time to time they were replaced by younger men with similar training, so that the most up to date experience was always available Medical officers not trained as pilots were encouraged to fly as passengers whenever this could be arranged

Vacancies for Geriatric Physicians

Replying to a question, Mr **R H Turton**, Minister of Health, said that 7 posts of assistant physician (geriatrics) were vacant throughout England and Wales There was 1 vacancy in the Newcastle, Leeds, Sheffield, South East Metropolitan, and South Western regional hospital board areas and 2 in the Manchester area

Appointments for Registrars of Non-teaching Hospitals

Replying to a question, Mr **Turton** said that 52 consultant posts in general surgery had been filled in the last two years Of those appointed at least 13 had held appointments as senior registrars in non teaching hospitals

Mr **S J McAdden** Is the Minister aware that there is considerable frustration among registrars in hospitals other than teaching hospitals, in that they feel they are not getting a fair crack of the whip in respect of these appointments? Has the Minister in mind some method of improving the position of such men, who, in other than teaching hospitals are doing a considerable amount of surgical work, and whose salary in some cases is considerably less than £1000 a year? Mr **Turton** The selection of senior registrars is made on the advice of statutory appointments advisory committees, on which the majority of members are medical men

Proposed Closure of a London Hospital

Replying to a question Mr **Turton** said that he was considering the views which had been expressed regarding the proposal of the North East Regional Hospital Board to close the St George in the East Hospital London, E 1, at the end of July, 1956 He hoped to reach a decision shortly

Retirement Pensions

Mr **S T Swingler** asked the Minister how many doctors and dentists in the National Health Service would be eligible for pensions on retirement in 1958, and what proportions they were of the doctors and dentists in the scheme—Mr **Turton** replied About 3500 doctors and 1500 dentists representing approximately 14% and 17% respectively These figures do not include doctors and dentists employed full time in hospitals

Suggested site of the lesion in skiing strains of the knee, showing directions of extravasation of blood

hæmatoma caused at the time of injury probably tracked downwards along the line of the ligament

Abduction of the knee caused pain in all patients If the pain was severe, preventing relaxation of the internal lateral ligament, an examination under anæsthesia was made No complete tear of this ligament was found

Effusion into the knee joint was present in all cases, and was first detected between one and six hours after injury The accompanying figure shows the suggested site of the hæmatoma, its probable entry into the joint, and its track along the fibres of the ligament

In 2 patients there was a more rapid onset of tense effusion and hæmarthroses were aspirated. 2 other patients had large bloodstained effusions aspirated some days after injury Patients with hæmarthrosis differed from those with severe strain only in the rate of onset and the tension of the effusion.

20 patients with severe injuries were examined radiographically, but in no case was any flake of bone detached from the insertions of the internal lateral ligament Within the period of the follow-up no case of calcification in the ligament (Pellegrini Stieda syndrome) was found

Treatment

Complete rupture of the internal lateral ligament was first excluded and the fluid was aspirated where necessary A firm, well-padded crêpe or flannel bandage was applied and the knee kept on pillows in full extension Early quadriceps exercises were started with particular emphasis on vastus-medialis control, these exercises were supervised by a physiotherapist

When quadriceps tone returned and the effusion had subsided, the patient started walking and the exercises were intensified Skiing was again allowed when quadriceps tone was good and there was no return of effusion after full activity In many cases there was still tenderness in the joint line at this stage

Early in the season 2 patients with severe strains were treated in plaster-of-paris cylinders for four weeks, in accordance with the practice in some Austrian centres Both patients were comfortable until the plaster was removed, when considerable quadriceps wasting was found with instability of the knee-joint Despite physiotherapy for weeks, 1 of these patients had to be physically downgraded

Follow-up

The time the patients were off full duty varied with the nature of their work and the severity of their injuries, the average time for a soldier on heavy duties was one month Patients with minor strains of the knee were often skiing again two weeks after injury, but only a few skied with any enjoyment in a shorter time this may be a useful guide to people sustaining injuries to the knee on short winter holidays 4 patients with moderately severe strains took part in competitive skiing between one and two months after their injuries

43 patients were seen at three to six months after injury All had functionally normal knees and were on full duties The patient who was downgraded was not followed up 20 patients still had slight tenderness in or below the joint line on the medial side 2 of these complained of such tenderness, and manipulation under anæsthesia six months later relieved this symptom 2 other patients had tenderness after eighteen months but functionally normal knees No patient had symptoms suggesting a cartilage tear

Meniscectomy was not carried out on any of my patients

Review of Previous Cases

In the preceding year meniscectomy had been undertaken on account of skiing injuries in 6 cases at the Military Hospital at Klagenfurt

Case 1 had previously had a "soccer" injury with locking of the knee, locking while skiing was precipitated by performing a "kick turn"

Case 2 had a definite "bucket-handle" tear of the internal cartilage, but he had had knee symptoms, particularly after playing "soccer," before starting to ski

Case 3 was operated on two weeks after injury He had pain and effusion Extravasation of blood was found under the capsule of the joint; the internal cartilage was removed, but no tear was found.

Case 4 was operated on a month after injury He had pain and effusion The internal cartilage was removed, but no tear was found

Case 5 was operated on a month after injury The internal cartilage was loose peripherally, but no tear was found.

Case 6 was operated on six weeks after injury, on account of instability of his knee-joint The internal cartilage was loose peripherally, but no tear was found. This patient tended to exaggerate his symptoms and he failed to coöperate in postoperative physiotherapy He was off full duty for six months, but when I examined him nine months after meniscectomy he had a functionally normal knee He skied throughout the next season without his knee troubling him

Discussion

Wiles (1949) states that the semilunar cartilages are seldom damaged in skiing injuries to the knee, although such an injury is often diagnosed. He says that the injured knee is relieved of the weight of the body at the time of injury, and the cartilage is endangered only by a strain during a Telemark turn when the weight is on the leading leg The coronary ligament or the internal lateral ligament is the structure likely to be damaged

Morrison and Coughlin (1950) reviewing 254 injuries in experienced skiers and novices, reported only 47 strains of the internal lateral ligament They note that most of the severe injuries of all types were to experienced skiers travelling at high speed They subsequently found that in 3 cases of knee strain there were cartilage tears, but they do not exclude previous trauma 1 of their patients had a complete rupture of the internal lateral ligament with disruption of the joint Their treatment of strains of the knee was more conservative than mine, and they used plaster-of-paris cylinders in severe cases They do not report any follow-up

Conclusions

The common skiing injury to the knee in a novice is a tear of the short capsular fibres of the internal lateral ligament True tearing of the avascular part of the cartilage is unlikely to result directly from the injury, but dislocation of a previously torn cartilage may be precipitated

The mechanism of the injury, in which abduction is a constant factor, suggests that the internal cartilage is not in danger of being trapped between the tibia and the *rotating* femur as in "soccer" or similar injuries This is substantiated by the fact that in two seasons no case of *cartilage* tear was found that could be directly attributed to a skiing injury I suggest that the site of the lesion is the attachment of the short fibres of the ligament to the cartilage, the bruising and hæmarthrosis show that the site is vascular, and rapid healing can be expected

Where it is certain that there is not a complete tear of the internal lateral ligament, patients are most satisfactorily treated by the restoration of quadriceps tone and early mobility The application of plaster cylinders in incomplete tears causes quadriceps wasting, even if quadriceps drill is practised while the cylinder is on, and the knee is unstable when the plaster is removed

I would like to thank Brigadier J H Huston for permission to study the patients, and Lieut Colonel J M Matheson, R A M C, for his encouragement

THE RISE AND FALL OF MENTAL NURSING

RICHARD A HUNTER
M D Lond, M R C P, D P M
LATE ASSISTANT TO THE DIRECTOR, YORK CLINIC, GUY'S HOSPITAL, LONDON

THIS series of articles, and especially those by Dr Bickford[1] and Dr Cameron and his colleagues,[2] demonstrating the vital rôle of nurses in the recovery of mental hospital patients, has brought a breath of fresh air into this electrically charged field Their nurses achieved much with chronic patients, how much more may be expected from a similar approach to early cases It is therefore the more urgent to ascertain the deeper cause of the present decline of mental nursing as a profession This decline, over the past twenty years coincides with the spectacular rise and spread of "modern physical methods of treatment" Is there perhaps an inverse relation between the two?

1956 is a suitable year in which to appraise the present situation, for one hundred years ago was published the most important over-all contribution to the welfare of mental hospital patients ever made *The Treatment of the Insane without Mechanical Restraints*, by John Conolly

Briefly, before the 1830s, as far as this country is concerned, difficult, violent, delirious, or suicidal patients were automatically clapped into various restraining devices ranging in general from chains to strait waistcoats, and in detail according to the technical ingenuity of the physician Patients were regularly bled, purged, vomited, blistered, and drugged That the popular mind erroneously equates insanity with violent behaviour arose in part from the cruelties practised on patients and their reactions to a punitive, suppressing environment

THE MOVE AGAINST RESTRAINT

The first *attempt to* establish the study of the insane as a specialty was made by William Battie, incidentally one of the very *few* psychiatrists to become President of the Royal College of Physicians of London He wrote that "such unhappy objects ought by no means to be abandoned, much less shut up in loathsome prisons as criminals or nuisances to the society" His kindly spirit led him to proclaim[3] that "the regimen in this is perhaps of more importance than in any distemper" Pargeter,[4] in 1792, wished to "abolish at once recourse to chains and cords," and Arnold,[5] in 1809, felt they "should never be used but in the case of poor *patients*" The Retreat at York, opened by the Society of Friends in 1796, was the first institution in which insane persons were treated as human beings by a "regimen" of "moral treatment," and thus was the birthplace of all subsequent reform culminating in the great movement for "non restraint" Tuke's stirring and challenging account[6] of the practice of the Retreat inspired all subsequent work with the insane and led directly to Conolly's great reform By the 1830s its kindly spirit had spread to the doctors of Lincoln Asylum In 1839 Conolly at Hanwell Asylum made the bold and successful experiment of putting into practice the *principle of non restraint in a large mental* hospital—acknowledged the world over as the major advance in the history of the guardianship of the insane The attitude of attendants changed from that of keepers to that of nurses, violence became exceptional, refractory patients took their place and worked in the hospital community, the recovery-rate rose to more than two thirds of all admissions

"The great principle of the non restraint system is to exclude all hurtful excitement from a brain already disposed to excitement On this principle it abolishes mechanical restraint and *also, on this principle* it regulates every word, look, and action of all who come *in contact with the insane*"[7] The *influence of a healthy* person's mind became the chief therapy in mental disease, and the mental nurse its most important agent

> "The physician who justly understands the non restraint system well knows that the attendants are his most essential instruments They may often be considered, indeed, his best medicines He confides the most confidential duties to them he entrusts them with the happiness, by day and by night, of all the patients under their especial care To control the violent, without anger, to soothe the irritable, without weak and foolish concessions, to cheer and comfort the depressed, to guard the imbecile and the impulsive, and to direct all"[7]

TRAINING OF NURSES AND DOCTORS

Thus the demand arose for mental nurses and their organised training In 1854, Dr W A F Browne, at Crichton Royal Mental Hospital, commenced a course of lectures comprising "a full, if popular, discussion of insanity in the different forms, intelligible by the shrewd and sensible, if somewhat illiterate class of persons employed as attendants and nurses"[8] In 1891 the Royal Medico Psychological Association held the first examinations which "remained for many years the only, uniform national system of training and certification of *any body of nurses in any country*" †[9]

The training of mental nurses was paralleled by the training of *mental hospital doctors*

> "The resort to instruments of mechanical coercion was inconsistent alike with any *medical consideration of the various* forms of mental *disease*, and *their* causes, as it was with attention to the numerous *auxiliary or moral means of cure* which are so greatly relied upon where the ancient methods of

In England Now

A Running Commentary by Peripatetic Correspondents

Of late years the number of physicians has risen steeply and now it is an impossible task for a national association to arrange meetings for all of them Indeed if pædiatricians neurologists, dermatologists and research-workers are included there must be over 1000 This probably was foreseen by Dr Hugh Barber of Derby when he founded the East Midlands Physicians' Association sixteen years ago For some time it met twice yearly in the county towns of Leicester, Derby Nottingham, and Lincoln These four counties and little Rutland later joined with South Yorkshire to form the Sheffield region, and that city is now included in the rota of meeting-places

The West Midlands Physicians Association was founded six years ago and though it admits to its meetings a limited number of pædiatricians pathologists, radiologists and other specialists its founder members were all physicians Its meetings are held twice a year one in Birmingham and one in a peripheral hospital It has visited Stoke-on-Trent, Wolverhampton, Coventry, Shrewsbury and Leamington This year it has met at the Royal Stafford Infirmary where Fowler of Solution fame Erasmus Darwin, and William Withering were physicians

The meetings are developing a routine We forgather at 10 30 A M for 11 A M for a cup of coffee Papers occupy the rest of the morning Lunch is always eaten standing up so that physicians can move about to talk to friends for with the years many acquaintances have ripened into friendships Further papers are given in the afternoon and after tea in the winter meeting in Birmingham This is also the occasion of the annual dinner, to which we have three times welcomed the president of the Association of Physicians of Great Britain and Ireland

Perhaps the highlight of our social activities was the spring meeting at Leamington last year, when a party of over 70 physicians and their wives, collected for dinner at Stratford on Avon to see *All's Well That Ends Well* ' That title expressed what many felt Even if there cannot be a national association for all regional societies offer an ideal alternative method of advancing medicine and promoting friendship

* * *

On getting home from the maternity hospital, a mother noticed on her baby's back two small red papules These were symmetrically placed one on each side near the angle of the corresponding scapula Somewhat worried and puzzled, she consulted her doctor who thought they were pressure sores and prescribed appropriate treatment This, however failed to arrest the development of the papules which became more prominent Seeking a second opinion, the mother was astonished and alarmed to learn that her infant had been born with two additional nipples The second opinion added that there was nothing much he could do about it and counselled resignation to the Divine Will

There the situation rested till the mother and infant duly attended the B C G clinic and the nipples " were measured and the readings recorded, as required, on form B C G 4 The mother's relief was considerable

Now we make only one mark, and tell everybody everything

* * *

I laid down my pen

' Just tell me what you think of this will you ? *THREE MONTHS' PRACTICAL COURSE for Prospective Brides and Housewives in the Domestic Sciences, including the Cookery and Service of Meals, the Ablution of Crockery, Silver, and Cutlery, the care of Footwear, Furniture, and House Fabrics, Labour saving Bedmaking* and a few more attractive items we must think up *Fees, 30 guineas, inclusive of Full Board and Lodging* That's only 10 guineas a month, and dirt cheap But what have I left out ? "

' Answering the telephone "

Legible transcription of telephone messages What about car cleaning and maintenance ? "

" Not ' replied my wife firmly ' within the terms of reference "

' A pity Then how about whitewashing at weekends ? When I could lend a hand ?

' No ' But you've forgotten the ordinary Monday mornings '

Oh yes, stupid of me Let's say, *Labour saving Bed making and Laundry*

Whose labour are you saving ? '

' Yours of course We must have seminars in something - I know, *Seminars in First-aid and Sick Nursing* We could easily get Aunt Madge to come and stay '

Not a bit of it I'll gladly oblige for a week or two '

" Fair 'do's We'll take it turn and turn about *Vacancies for* two ? three ? how many could you be doing with ? *Vacancies for* (say) *two students on Feb 1st Apply Box Number* '

Where are you going to stick this ? she asked

' *Times* agony column of course

" How much is it going to cost ? '

" Dunno About two or three pounds I suppose '

' You can buy us a really good dinner for two or three pounds You can be getting the car out '

But I wish we had tried it just to see what happened

* * *

Now that we have put away our boots and listened to our wives telling us what fools we are to go on playing at our age we have a chance to ponder philosophically over the lure of the oval ball

For many years I have been convinced that as a sect, we rugby players must be kinder to our wives than the average husband Our incidence of divorces, wife-beating convictions, and bills for post-argument fur coats must be significantly below the average All the frustrations of the week's work are vented to atmosphere on Saturday afternoon Pity the opposing forward who lies on the ball a second too long the wing forward who always seems to be off side (' O K skipper I'll get him next scrum ') and so on When it's all over one returns home in a state of monastic calm framed by a few convivial pints and ready for the problems of next week Will some enterprising statistician please do a controlled study to prove my hypothesis

' What's that, dear ? Of course I ll need them next season, after all, I'm only 35 "

* * *

The patient who knows the answers can be a great help to the peripatetic paperhanger and ours listened unsympathetically to our account of blisters on the wall and the needling technique which we developed for reducing them (see this column May 26) He was unimpressed by the undoubted success of the manœuvre ' Your paper wasn't wet enough," he said, ' unless a thick paper is pretty well soaked through that sort of thing can happen What you should do is measure and cut five or six strips of paper at a time and paste them all By the time the fifth has been pasted the first will be ready to go up after a second coat of paste "

Paperhangers, by the way, vary in status There are the consultants, such as my patient, who do difficult and complicated operations on ceilings, and then Registrars who work on walls but make perfect butt-joins with matching of patterns. Mere practitioners in paperhanging prefer unpatterned paper and allow a good half-inch of overlap In spite of our original contributions to the subject we foresee no upgrading until we have mastered butt-joins

* * *

News from School —After the exams, during the somewhat empty weeks before the end of term, certain of us plan to make *many hundred* pounds of fudge and toffee, sell it, and buy a well for an Indian village Others of us intend making teddy bears to the same end, but I reckon the market for fudge has a more secure bottom A good watery well costs £70 we are told and saves a five mile walk to a cholera ridden water hole —through, as our informant made no bones about telling us (unfortunate phrase ?) man eating tiger territory and prednisone inhibit spontaneous fibrinolytic activity in cirrhosis, they do not significantly reduce the intensification encountered in response to the injection of adrenaline We very much doubt therefore, whether this mode of treatment would be successful in preventing or controlling the hæmorrhage associated with intense fibrinolysis which has been frequently reported by surgeons operating on patients with cirrhosis although the mechanism was unrecognised

RHESUS(D) FACTOR IN SARCOIDOSIS

SIR,—Through the courtesy of the physicians of the Brompton Hospital I have examined the records of 64 patients with sarcoidosis in whom the blood-groups have been determined Histological evidence had been obtained in 46 (72%) of these Lungs or hilar lymph-nodes were involved in all cases The blood groups were as follows

Rh(D) factor		*A B O group*			
Negative	*Positive*	*O*	*A*	*B*	*AB*
11 (17%)	54 (83%)	38 (59%)	22 (34%)	3 (5%)	1 (2%)

In comparison, the blood-groups of 419 inpatients of this hospital, determined during the past three months, were as follows

Rh(D) factor		*A B O group*			
Negative	*Positive*	*O*	*A*	*B*	*AB*
71 (17%)	348 (83%)	199 (48%)	164 (39%)	39 (9%)	17 (4%)

These figures support those reported by Dr Smellie (June 2) from King's College Hospital, showing a similar prevalence of Rh(D) negative blood in the patients with sarcoidosis to that in the general population, and are additional evidence against the suggestion by Dr Cudkowicz (April 21) that this blood-group might be more frequent in patients with sarcoidosis

EXTRADURAL HÆMATOMA

SIR,—Mr Whalley (May 26) remarks that unskilled anæsthesia in this condition causes increased cerebral congestion which may lead to tentorial herniation.

We feel that it is so essential in these cases for the airway to be perfectly clear that an experienced anæsthetist should always be present and should pass a cuffed endotracheal tube after clearing the mouth and pharynx of all obstruction In some cases this can be done after spraying the larynx with local anæsthetic solution, but in others the administration of a small amount of muscle relaxant with or without a minimal quantity of thiopentone may also be necessary A suction apparatus should be ready in case the patient vomits at this stage The improvement in the patient's condition after intubation is most gratifying, and troublesome hæmorrhage during operation is minimised The endotracheal tube should be connected to an open-circuit type of anæsthetic apparatus (we employ Ayre's T piece for this purpose) Oxygen and, if necessary nitrous oxide or trichloroethylene is administered It is most important to avoid any positive pressure in the anæsthetic circuit The proposed scalp incision is then thoroughly infiltrated with a local-anæsthetic solution When the cerebral compression has been relieved by the surgeon any tendency of the recovering patient to struggle before completion of the operation can be controlled by the administration of fractional doses of muscle relaxant and/or thiopentone

This procedure has been followed in 13 out of 14 consecutive cases of extradural hæmatoma operated on by one of us, with recovery in all but 1—a child aged 6 years whose compression had been present for thirty hours when first seen

The guiding principles we believe, should be the establishment and maintenance of a clear airway, the administration of a high concentration of oxygen, the avoidance of all struggling and straining, and the use of the absolute minimum of anæsthetic agents In this way cerebral venous congestion is diminished and good operating conditions are obtained

PATRICK CLARKE

Newcastle General Hospital

FEMALE CHROMATIN IN MALE EUNUCHOID

SIR,—The implications of the following case seem to us sufficiently far reaching to justify its brief and early publication in the hope that investigation at other centres may yield confirmatory findings

The patient aged 35 is apparently a typical male, obese eunuchoid He has not undergone puberty Both breasts are enlarged, but the tissue composing them is solely fat (confirmed by biopsy) The penis is small and the fully descended testes soft and tiny, but there are no external features whatever of hermaphroditism—no evidence of persistence of mullerian duct structures Laparotomy (Prof J H Louw) revealed no female organs in the pelvis in particular no uterus, and no third gonad even in the renal area The follicle stimulating hormone in the urine was positive at 48 mouse units (Dr A Kipps)

Bilateral testicular biopsy was performed and histological examination showed total absence of spermatogenesis, with a reduced number of tubules composed entirely of Sertoli cells The Leydig cells were massed together in clumps and appeared to contain a good deal of lipoid There was no hyalinisation or fibrosis (unlike the typical appearance in the Klinefelter syndrome) No ovarian tissue was seen

Most unexpectedly in an excellent section of skin some 60% of cells contained the typical female sex chromatin ' This has been confirmed by a second piece of skin from the other side of the body

This patient thus illustrates prepubertal primary hypogonadism in an anatomical male with no trace of hermaphroditism, yet whose cell nuclei are of the type associated with the genetic female

BREAD

SIR,—The report of the Panel on Composition and Nutritive Value of Flour is not clear on one point The panel state that they were "impressed by the evidence for the demand for white flour and white bread" Yet they do not give this evidence in their report Were the results of any surveys of consumers' demands available to them? The only quantitative evidence which they give is to be found in Appendix I of their report This shows that in 1953 the sale of unsubsidised white bread was 4 4% of total sales and that by 1955 this figure had fallen to 0 8% According to the report, a $1^3/_4$ lb loaf made from subsidised National flour cost 7½*d*, whereas loaves from flours of lower extraction-rates cost from 10½*d* to 1*s* *For a large family this price differential is* clearly very important But for an individual eating half a loaf a day, it amounts to between 1½*d* and 2*d* a day—*approximately the cost of one cigarette* During the period *to which these figures apply, large sections of* the population were enjoying relative economic prosperity Yet only a very small proportion were prepared to pay the price equivalent of one cigarette to eat white bread *Further, this proportion fell steadily during the* period This quantitative evidence, which the panel give in their report, would appear to indicate that the demand for white bread from the public was very small *Could the panel explain their reasons for neglecting this* evidence, which they give without comment, and could they give us the evidence for the popular demand which so impressed them? At the moment, their report appears *to rest on a basis of surmise, and one foundation stone* of fact seems to have been rejected

Edinburgh University

R PASSMORE

RESPIRATORY INVOLVEMENT IN POLIOMYELITIS

SIR,—*Professor* Trueta and *Dr* Agerholm (June 2) state that tracheotomy, by leading to chronic pulmonary infection with further diminution of ventilation, can be a tragic complication in cases of severe residual paralysis *following* poliomyelitis and that, in the absence *of an effective cough, closure of the stoma may be* dangerous It could be added that aspiration may have infected the lungs before tracheotomy is performed and *the stoma then allows the frequent removal of con*taminated bronchial secretions by deep suction which, in the acute phase, is necessary at intervals throughout the 24 hours

The possibility mentioned *by Professor Trueta and* Dr Agerholm of leaving an orally introduced tube in situ seems impracticable, since the period of bulbar paralysis, though limited, may last for weeks, during which *the patient* would *presumably* have to remain anæsthetised, and there is also the likelihood of laryngeal ulceration

In *bulbospinal* poliomyelitis, tracheotomy is not done for the sake of administering artificial respiration by positive pressure but for the sake of a clear airway—of which, when accompanied by efficient bronchial suction, it is the best and sometimes the only guarantee As Professor Trueta and *Dr Agerholm say, the decision* to perform a *tracheotomy must rest* with the man on the spot His first duty is to save the patient's life, if necessary by tracheotomy, which we believe should not be reserved *for situations without* full hospital facilities, but rather the opposite

Whitley Hospital
Coventry

J F GALPINE
H S KANDER

SIR,—May I add a short note to the wise comment on this subject made by Professor Trueta and Dr Agerholm, and incidentally fall in with their prudent suggestion that experience in this field should be pooled?

Certainly some cases of severe respiratory involvement need tracheotomy I think that, apart from urgent *transportation problems, these are relatively few* In the past, I have treated successfully with Dr Harwood Stevenson at the Royal National Orthopædic Hospital a group of cases of considerable severity by means of bronchoscopic suction supplemented by skilled physiotherapy It is possible to do this even when the patient is in a cabinet respirator and I have found that it is, to a surprising degree, a life saving measure It is an axiom of laryngology that tracheostomy or laryngostomy tubes must be removed at the earliest possible moment in order to avoid the well known harmful sequelæ These patients are obviously extremely vulnerable to these sequelæ and the nature of their lesion delays or prevents the closing of the tracheal stoma

It seems to me, therefore, that the adoption of tracheotomy as a prophylactic measure, or as anything approaching *routine,* would *be a serious mistake* The need for it can often be avoided by adequate bronchoscopic suction and judicious physiotherapy

London, W 1

A M ZAMORA

PHENOBARBITONE POISONING TREATED WITH BEMEGRIDE

SIR,—Dr Hurdle and Dr Lane are to be congratulated on their valuable and very interesting contribution to your issue of June 2 May I, however, venture to comment on a few points in their *discussion of the* case, which I feel may be important in treating future cases?

They very *correctly* state that bemegride does not appear to be toxic, and they draw attention to the danger that those *who treat such cases may fail to realise that the drug may have to be given for a long time to prevent regression* But I would not agree with their suggestion that it seems more sensible to mix the bemegride with the intravenous transfusion fluid in the bottle rather than to inject it intermittently Apart from the disadvantage this method would entail of not knowing what the effective concentration of bemegride has to be in the intravenous fluid (a difficulty *the authors themselves* encountered), had the intermittent method of administration[1] been continued (provided spasm *of the vein* had not *occurred), the boy might have recovered consciousness* earlier The criteria *of the* "safe state" have a very safe guide as my *colleagues* and I have always found, further courses of both drugs are given when regression sets in after the safe state had been once restored[2,3] It is important that the safe state be restored as soon as possible, for this minimises both the immediate risk to the patient's life and the remote risk associated with possible complications of prolonged barbiturate *coma*[1-4]—*hence the necessity* of removing the barbiturate effectively from the system as soon as possible

Besides these points, one should not entirely *dismiss* even the remote possibility of toxic signs developing The early signs are vomiting or retching, which may be accompanied by *slight flicker of the fingers*[1] and *twitching of facial and* limb muscles This was noticed in one of our patients successfully treated (a girl $2^1/_2$),[3] to whom the drugs were given in the same course, after the signs of the safe state had appeared If intermittent administration is adopted, one can effectively discontinue the drugs before serious toxic signs develop

It is, I feel, unwise to use amiphenazole (in addition to bemegride) only when the respiration is depressed *It has been established that amiphenazole* besides being a respiratory stimulant is also a barbiturate antagonist

Obituary

KNUD FABER

M D Copenhagen, LL D Edin , F R C P E

Knud Faber was appointed regius professor of medicine in the University of Copenhagen in 1896 when he was 34 years of age During the 36 years he held office he influenced almost every side of medical life in Denmark, for he was a teacher as well as a scientist, an investigator as well as a clinician, and an administrator as well as a planner

[Schmidt New York

Besides holding the university chair he was chief of the medical department of the Royal Hospital in Copenhagen, and a fellow countryman K H K recalls that "he introduced laboratory investigations into daily clinical work and wrote the first manuals on laboratory methods He inspired an almost constant flow of contributions to contemporary clinical and theoretical medical science—articles, theses, and books And he lectured on clinical medicine for 36 years to every man or woman who qualified as a doctor in Denmark His own scientific work was mainly concerned with diseases of the alimentary tract—gastritis and peptic ulcer, colitis and anæmia, and diabetes mellitus

"His vivid and crystal-clear mind and his strong personality led him into a long and fierce battle for a system of medical administration which today is accepted by everybody in our country, but which caused a revolution 50 years ago He wanted a firm *medical* control of the administration of public health, of hospitals, nursing, pharmacy, dentistry, midwifery, and the treatment and prevention of tuberculosis He succeeded in creating each of these branches of medical administration, though it took 18 years of laborious negotiations

"Fifty years ago he organised the fight against tuberculosis , and he lived long enough to see empty sanatoria As dean of the University of Copenhagen he was an enthusiastic promoter of the development of the new university at Aarhus—Denmark's only other university—which is now flourishing In his old age he took a special pleasure in taking part in academic meetings at the Aarhus University After his retirement in 1932 his firm hand was still felt in decisions taken by his successors in his many fields of activity He wrote books on his public and private life, and even in his later years he spoke on several occasions Faber has served his country as very few have done, and his personal contribution to the promotion of the health of his countrymen has never been surpassed "

But Faber also served medicine outside Denmark In 1926 he gave a lecture tour in the United States and in 1931 he reported on the medical schools of China He had many contacts with his colleagues all over the world and was a member of the academies of medicine in Ireland Belgium Bologna, Stockholm, and Paris In this country the University of Edinburgh had conferred on him the honorary degree of LL D and he was a fellow of the Royal College of Physicians of Edinburgh and an honorary fellow of the Royal Society of Medicine He died on May 3 at the age of 93

BERNARD HART

O B E , L M S S A

Dr Bernard Hart, radiologist to Doncaster Royal Infirmary, died on June 6 at his home at Armthorpe at the age of 72 Like so many of the early workers in radiology he was disabled by the rays he studied and for many years he faced surgical and medical treatment for the burns and anæmia which he contracted

He joined the radiological department of Sheffiel Royal Hospital as a lad and later became radiograph there At first he was mainly interested in technic problems, but his work turned his attention more a more to the growing clinical possibilities of the new ray Shortly before the 1914–18 war he began to study med cine, but his qualification was delayed by active serv with the Royal Navy He finally took the L.M S S , 1923 and within a year or so was appointed to the staff Doncaster Royal Infirmary Despite ill health he carrie on his practice there for many years

EDWARD NORMAN JAMIESON

O B E , F.R C S E, L D S

For many years the name of Norman Jamieson h been a household word in the Outer Hebrides H work as surgeon to the Lewis Hospital was centred Stornoway, but his help and advice were availab to the most remote island croft from the Butt of Lew to Barra Head

He qualified, both in medicine and dentistry, fro the Edinburgh medical school in 1924, and after holdi resident appointments at the Edinburgh Royal Infirma he spent some years in Paris as resident surgical offic to the Hertford British Hospital He returned to Scotlan to take the Edinburgh fellowship in 1928 and the became registrar at Perth Royal Infirmary In 19 he was appointed to the Lewis Hospital in Stornow He found it a small cottage hospital with meagre faciliti Twenty-five years later, mainly thanks to his ener and foresight, it is an up-to-date general hospital wi 61 beds in its wards and plans for a further 30 a well advanced

Jamieson's professional life was shaped by his islan practice In the early years at least he had to offer h patients treatment in all surgical specialties with th help of a general-practitioner anæsthetist Indee at first he also acted as unofficial consulting physici to the hospital Later, modern transport and th improved facilities under the National Health Servic enabled him to bring his patients to hospital an increased his surgical scope His mastery of many specialties, and his enthusiasm for them al made him a valuable teacher, and his house office and registrars found Lewis an effective if unrecognis postgraduate school Despite many years of ill healt and his arduous and exacting work, he often visite the Edinburgh medical school for refreshment and stud and he was in Edinburgh when he was taken ill H died there on June 3 at the age of 56 He leaves a wido and a daughter

J C R-G writes "Norman Jamieson was a gener surgeon of the highest order Much of his work w obstetrics, a specialty in which he was particular interested and skilled, but he was equally at home gynæcology, orthopædics, ophthalmology, surgery the ear, nose, and throat, dentistry, and radiolog His work was done with meticulous care for detail an with insistence on the highest standards

"His visits to patients across land and water migh entail travelling by car, plane, or boat, over fords b horse and cart, or many miles on foot , journeys whic must have been a severe strain on his health Yet h courageously overcame the effects of a serious flyin accident and the tragic death of his younger daughte adjusting his life to ill health in a way that made o almost forget that he carried these additional burdens

"No matter how busy the day, he always remaine calm and unruffled , welcoming the visitor with a smi and anxious to show the stranger over the hospital— the growth and development of which he had pla such a large part and in which he was justifiably prou The kindness to the stranger and the welcome to h many friends reached their height in the hospitalit of his home where, in his quiet unassuming manne he would discuss photography fishing, and shootin He was a keen and knowledgeable sportsman and it w a pleasure to see him return to work refreshed an invigorated after a holiday in Harris the island he love so much and knew so well He will long be remembere with respect, gratitude, and reverence in every islan home ' and a good synergist to bemegride[1]—thus the cumulative effect of antagonising the barbiturate by a combination of both drugs would help to restore the patient to the safe state sooner After all, in a patient constantly liable to respiratory depression, no harm is done by using a respiratory stimulant, such as amiphenazole, which has been proved to be quite safe[1–3 5–]

FORT MIT DEM SPRAY!

SIR,—In your leader of June 2 prominence was most appropriately accorded to Henry of Mondeville and his progressive injunctions against surgical interference with wounds It may be of interest to record a previous appreciation of Mondeville in your columns[8] given on the occasion of the discovery and first edition of his great surgical work by Julius Pagel (1851–1912) Mondeville stands out as one of the most original figures in medicine and surgery of all times It should be added in fairness, however, that he continued the tradition of Theodoric and his predecessor Hugo of Lucca at Bologna It is the latter whom Julius Pagel called "the intellectual instigator of pus-less wound treatment" The *Surgery* of Theodoric embodying Hugo's views is now being translated into English (by E Campbell and J Colton) Books I and II have already appeared,[9] and I am reviewing them in the forthcoming issue of *Isis*

London N W 10
WALTER PAGEL

ANÆSTHESIA IN OBSTETRICS

SIR,—Perhaps your readers might be interested in the following simple method, which I have used and taught for many years, for preventing inhalation of vomit during obstetrical anæsthesia I call it the "two-pillow technique" and it is for use where the obstetrical bed cannot be tilted, when anæsthetising for forceps delivery, &c

One pillow is placed beneath the patient's scapulæ and a second pillow is placed under the patient's head The anæsthetic sequence is nitrous oxide, oxygen, trichloroethylene, and ether (or similar) from a semiclosed circuit The anæsthetist's attention is focused on the patient's breathing, and, in the light plane of anæsthesia used, impending vomiting or actual vomiting is immediately recognised with experience, by some irregularity in the breathing If this occurs, the pillow under the patient's head is immediately whipped away and the head turned to one side The patient is now in the "tonsil" position and any vomit will travel away from the larynx by gravity and can be dealt with by appropriate means

I regard this simple manœuvre as a safeguard to be used in addition to the usual precautions when anæsthetising patients who may have stomach contents, and I have not personally encountered any difficulty in managing such patients by this technique

River Hospitals
Joyce Green
Dartford Kent.
JOHN BULLOUGH

SIR,—Two questions which deserve answers have so far received little attention

Why is the danger from vomiting less when anæsthetics are given in domiciliary midwifery? Is not this fact related to the use of anæsthetic machines in hospitals by persons not familiar with them?

Vomiting under an open mask is quickly perceived and compels attention towards clearing the airway Vomiting under a mask strapped on to the face is often mistaken for coughing by the inexperienced administrator, who therefore sits tight and hopes for the best, with disastrous consequences

London S W 18
D A. BUXTON HOPKIN

PARAPLEGIA FOLLOWING SPINAL ANÆSTHESIA

SIR,—In his letter of June 2, Sir Francis Walshe refers to my citing my "single experience of the ampoule contaminated through invisible cracks by the coloured fluid in which it was immersed" Your readers should not infer that the incident is unique Came[1] reports 12 contaminated ampoules, revealed by discoloration of the contents, in his own practice as an anæsthetist while Steinberg[2] detected in this way 4 faulty ampoules in the course of "approximately 1000 spinal anæsthetics" Steinberg continues "If I had used the four ampoules mentioned, it is conceivable that I might have had 4 serious neurologic sequelæ which would have placed spinal anesthesia in a very unfavourable position"

Dr Lerman (June 9), having witnessed in the East an assembly of patients suffering from the complications of spinal analgesia, advocates that the procedure should be abandoned He makes no mention of the training, skill, and experience of the anæsthetists concerned Nor does he mention the number of silent witnesses in the local graveyards despatched by general anæsthetics incompetently administered Surely he would not, by the same argument, recommend that general anæsthetics should be discontinued

R MACINTOSH

HORMONES AND BREAST CANCER

SIR,—In your leading article of May 12, you rightly conclude that, despite increasingly radical surgery and more intense radiation, there is "little improvement in survival-rates and often only questionable benefit to the patient" Indeed, reading about the poor results after adrenalectomy or the destruction of the pituitary gland with radon implants or similar methods, one wonders whether the authors of these methods are not in danger of losing sight completely of more basic principles and reality, in the glamour of severe surgical procedures In these I include ultra-radical mastectomy, pelvic exenteration in advanced genital cancer, and bilateral oöphorectomy followed by adrenalectomy or hypophysectomy

For about seventy years the ovaries have been removed in recurrent breast cancer, in the belief that the flow of œstrogens is undesirable and may provoke further carcinogenesis But after removal of the ovaries it is above all the thyroid gland which begins to elaborate more thyroid hormone, which in turn acts as a metabolic anti carcinogen and improves the condition of the cancer patient Why then should one continue to remove the ovaries if simple thyroid medication has the same effect, especially when thyroid hormone is coupled with androgens?

Already in ancient Egypt women with breast cancer were given seaweed in order to increase the working capacity of the thyroid gland by means of the iodine content of the seaweed, and an improvement in cases of breast cancer was observed (Ebers Papyrus)

Furthermore, as you remark, we know that after bilateral oöphorectomy the adrenals elaborate more undesirable steroid ovarian hormones, counteracting our endeavours to eliminate from the body the last traces of œstrogen After adrenalectomy, it is the thyroid gland—to a certain extent an antagonist of the suprarenal gland—that elaborates more thyroid hormone than before Why then is *it* necessary to remove an endocrine gland, especially the adrenal gland, when thyroid by mouth improves the hormonal metabolism of the cancerous body at least *to* the same extent, if not to a great deal more?

Adrenalectomy in cases of advanced cancer is a retrograde step The immediate disappearance of pain after adrenalectomy is due to the administration of cortisone, but cortisone could be given together with thyroid if one

BENNO SILBIGER

M.D Prague. LL.D Graz M R C S

Mr Benno Silbiger, consultant ear, nose and throat surgeon to Paddington Green Children s Hospital and associate chief assistant to the E N T outpatient department of St Bartholomew's Hospital London died on May 10

He was born in Brno Moravia, in 1895 and studied law in Vienna and Graz, where he took his doctorate in 1919 Attracted to medicine he began his medical studies at the University of Vienna and continued them in Prague graduating M D in 1923 The same year he joined the E N T department of the German University clinic in Prague and two years later, with a Czechoslovak State scholarship, he was sent to Vienna for postgraduate training at the laryngo-rhinological department under Hajek, and the department of otology under Neumann In 1926 he returned to Prague where he became deputy director and later acting director of the university E N T department

In 1939 political events forced him to leave and he came to England where he took the Conjoint diploma in 1942 from St Bartholomew s Hospital Medical College In 1942 he was appointed E N T surgeon to the Central Middlesex Hospital an appointment which he held until 1946 when he joined the staff of Paddington Green Children s Hospital He was also honorary consulting E N T surgeon to the School of Opera

W G writes "Not only was Benno Silbiger a well known E N T surgeon he was also well known as a lover of music and he seldom missed a concert or operatic event He had personality, charm and wit and he leaves many friends and colleagues to whom his death came as a sad shock In their memory he will always be cherished"

Notes and News

THE HEBERDEN SOCIETY

THE annual Heberden Round was conducted by Dr GEORGE KERSLEY at the Bath Royal United Hospital on June 1 The round is a clinical tour de force at which uncommon or controversial aspects of one or more mesenchymal diseases are discussed before an informed and critical audience After the round some scientific papers were presented

Dr D P PAGE THOMAS and Mr J T DINGLE (Bath) described their studies of the in vitro respiration of normal and rheumatoid synovial membrane The diseased membrane was found to have a relatively higher rate of anaerobic respiration They also demonstrated the effects of serum from rheumatoids and normal controls upon the growth of embryonic bone This work was still in its preliminary stages and no conclusions were drawn Dr D G SCOTT and Dr A G S HILL (Stoke Mandeville) were concerned with the possible antigenic potentialities of synovial membrane They had injected human synovial tissue into rabbits Antibodies from the rabbit serum were later tagged as globulin, with fluorescein and applied in solution to microscopic sections from a number of human organs The labelled antibody globulin was seen to react specifically with reticulin Antibodies to renal glomeruli similarly prepared did not so react

The shortcomings of cortisone in the treatment of rheumatoid arthritis has directed attention back to gold Dr M R JEFFREY (Bath) described his work on the distribution of ^{198}Au labelled calcium aurothiomalate after its injection into laboratory animals No significant localisation was found The presence of inflammation appeared to hasten the absorption and excretion of the injected gold, normally a very slow process

The apparent specificity for rheumatoid arthritis of the modified Rose-Waaler tests led Dr ROWLAND ALEXANDER (Edinburgh) to attempt to track down and isolate the agglutinin responsible He described the methods used to precipitate the active fraction from the serum proteins and to partially purify it by electrophoresis on filter-paper The highly concentrated fraction was tagged with fluorescein and then allowed to react with sensitised sheep red blood-corpuscles as in the Rose Waaler test As yet he has not been able to locate the specific fluorescent material on the agglutinated cells

Reports that the metabolism of 17-ketosteroids in gout was abnormal led Dr E R COOK (Bath) to study the pattern of excretion of 17 ketosteroids in this disease By chromatography he measured the relative concentrations of dehydroisoandrosterone etiocholanolone and androsterone, the three major components of urinary 17 ketosteroids His preliminary results showed no difference in the pattern of gouty and normal individuals

Mr J H PEACOCK (Bristol) spoke of his investigations of the peripheral circulation, by arteriography and plethysmography in Raynaud s disease acrocyanosis and rheumatoid arthritis, and in normal individuals Contrary to expectation, he did not find that the incidence of abnormalities among the rheumatoid patients he studied differed appreciably from his controls Dr J H GLYN (London) followed the course of rheumatoid arthritis, in a group of patients receiving cortisone with a battery of serological tests The tests did not prove of any practical value in distinguishing between non-specific disease suppression and true disease remission; Finally Mr NORMAN CAPENER gave a delightful account of the integrated movements of the pelvic and lumbar joints of erect man in action He emphasised the importance of this subject to the understanding and treatment of disorders of the hip joints

DESIGNING CENTRES FOR PRACTICE

IF in the National Health Service, an architect makes a building cost more than it need, he is depriving the public of some other building somewhere else In an address to the Architectural Association in London on May 30 Dr STEPHEN TAYLOR said that the new challenge to architecture was to combine efficiency with economy—and humanity The purpose of a N.H S building was not to glorify the doctors the committee or the architect, but to serve the *patients* (One way of judging whether it was good or bad was to see who was going to use the front door) The efficiency needed could be attained only by endless attention to detail does not prefer really massive doses of testosterone with thyroid.

And now all the furor against endocrine glands is directed against the hypophysis, and destruction of this gland is attempted with sword or atomic fire. But here again, after destruction or removal of the gland, it is thyroid and cortisone which must be administered to keep the body going. Technical surgical perfection, at which we all aim, cannot replace common sense in cancer therapy.

After all, cancer is essentially a disease of cell metabolism brought about by some failure in the intracellular enzyme systems, which are under the control of the thyroid gland, so surely it is to this that our activities should be directed?

As far back as 1932, it was shown by means of the Warburg apparatus that hormones influence cell respiration. The transformation of a normal cell into a cancer cell depends on the respiratory quotient of the tissue. How far hormones, and especially thyroid, can influence cell respiration and fermentation, via phosphorylation, cannot for the moment be said. But it seems to me that cancer formation starts and goes on when a carcinogenic substance hits continuously thyroid-deficient tissues. If that is so, our therapeutic marching orders are clear.

London, W.1 A. A. LOESER.

TREATMENT OF NEPHROSIS WITH PREDNISOLONE

SIR,—Dr Arneil (April 14) does considerable service to the interests of prednisolone in the treatment of nephrosis by drawing attention to the effect of this drug on the albuminuria.

Owing to the salt-retaining effect of the earlier cortisones, as a result of which a diuresis, which was believed to be the beneficial result, tended only to take place when the treatment was stopped, there has been a tendency with many to feel that steroid therapy merely acted like mersalyl, urea, and other diuretics of limited value in this condition. As was clearly evidenced, however, in cases recently under my care treated by prednisolone, the effect on the albuminuria is obviously a most valuable one, and, even though this may have no specific effect on the disease proper, the fact that the drainage of albuminuria is at least in part a cause of the œdema would suggest that its relief must have a decidedly beneficial effect on the outcome of the illness, when one remembers that one of the chief causes of its mortality (though admittedly less since antibiotics were introduced) was the liability to intercurrent infection to which the waterlogged and bedridden patient was particularly exposed.

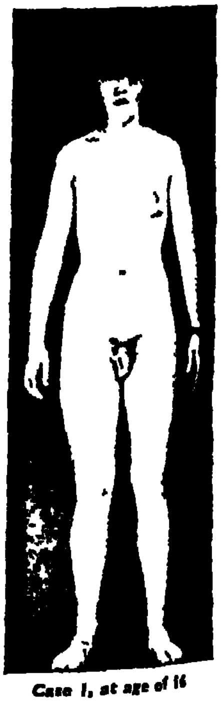
Dr Arneil treated his cases by continuous dosage for a period rather than by intermittent therapy (for example, three days a week) which the older diuretic concept made a popular regime. As with other chronic conditions amenable to steroid therapy, the continuous method would seem to be the more rational. He gave the impression, however, that all his cases were cured after the forty days' treatment. It would be interesting to know if they were followed up long enough to be certain that relapse did not take place later. This occurred in one of my cases where, when dosage was reduced to a practicable maintenance level, moderately heavy though much less severe albuminuria recurred.

Though of course no criticism of Dr Arneil's paper, an interesting and unexplained feature is why, unlike steroid therapy which in most cases seems to have to be continued for long periods, the originally used measles often cleared up the condition completely with one single "shock" as it were. This was very striking in a case under my care in 1933 when I was physician to Dr Steeven's Hospital, Dublin. This child had been waterlogged with œdema and had had profuse albuminur for months. After the child contracted measles the œdema and the albuminuria cleared up in a most remarkable manner in a matter of a few days. When seen recentl he was found to be a perfectly healthy adult. The detail of this case, which if published at the time might possibl have been the first recorded case of the effect of measl on the nephrotic syndrome, are appearing in the Ir Journal of Medical Science as a historical note.

Dublin R. E. STE

NUCLEAR SEX IN KLINEFELTER'S SYNDROME

SIR,—A syndrome characterised by gynæcomasti small testes with aspermatogenesis, normal or moderatel reduced function of the Leydig cells, and increased excretion of *follicle-stimulating hormone* was fir described by Klinefelter et al.,[1] who reported 9 ca In testicular biopsies hyalinisation of the seminiferou tubules was seen, and breast tissue showed hyperpla of the duct epithelium and much proliferation of th periductal connective tissue. Klinefelter et al. regarded the degenerative lesion of the seminiferous tubules a primary, and the gynæcomastia as due to secondar hormonal disturbances. Nelson and Heller[2] and de la Balze et al.[3] reported additional cases of Klinefelter's syndrome. They agreed that the disease should be regarded as primarily affecting the testes, and suggested that abnormal proliferation of fibroblasts in the tubular wall led to complete hyalinisation and atrophy of the germinal epithelium.



Case 1, at age of 16.

The technique of determining chromosomal sex from smears[4] has thrown new light on different forms of genital malformations. In accordance with a suggestion by Prof. M. L. Barr,[5] we have recently examined two patients with Klinefelter's syndrome.

CASE 1.—No previous illness during childhood; lived as a normally developed boy. From age 11 increasing growth of mammary glands. At age 14–15 spontaneous male pubertal development: deepening of voice, enlargement of genitalia, growth of pubic hair, &c. Admitted at age of 16 on account of gynæcomastia.

On examination, general somatic development corresponding to that of a boy aged 15, except for somewhat broad hips (see figure). No obesity. Height 168 cm., no eunuchoid skeletal proportions. Development of secondary male sexual characteristics, including muscular strength, normal for age. Penis (61 mm. long) and scrotum well developed. Testes very small (diameter 9–10 mm.), firm. Large bilateral gynæcomastia vera, corpus mammæ about 6 cm. in diameter.

Hormone excretion per 24 hours: total neutral 17-ketosteroids 9.3 mg.; androsterone 2.5 mg., etiocholanolone 2.8 mg.; gonadotrophins 25 mouse units.

Testicular biopsy.—Complete hyalinisation of seminiferous tubules; no spermiogenesis. Interstitial tissue filled with dense masses of Leydig cells.

Course.—Followed 2½ years after surgical removal of mammary glands. Despite normal 'male' excretion of

The general practitioner carried an enormous burden of serious illness, including most terminal illness Ideally he should have as his agents and helpers the home nurse, the health visitor, and the midwife, he should run clinics for his own mothers and babies, and he should look after his patients at work as well as at home All this was now generally accepted but far from generally achieved The years since 1950 (the turning point for general practice) had seen very important advances—the growth of rota schemes, the growth of group practices, the holding of clinics by practitioners for local authorities, and experiments with health centre buildings designed to bring practitioners and local authority services together The parts of the local authority services concerned with patients had come into being to fill gaps left by National Health Insurance general practice, and under the N H S the family doctor should in theory cover them himself In practice it was an immense help to have the assistance of local authority staff The family doctor could run maternity clinics (on local authority premises or his own) with the health visitor and/or midwife in attendance, and health visitors could act as general practitioners' social workers just as district nurses (home nurses) acted as their domiciliary assistants

All this depended largely on proper accommodation and in the National Health Service Act stress had been laid on health centres Unfortunately, the cost of the first N H S health centre planned in London was prohibitive to accommodate all practitioners on the same scale would have cost about £600 million The large centre built in Edinburgh had also been too expensive to reproduce Hope for the future, Dr Taylor thought, lay in the more modest health centres or group surgeries established publicly or privately in various parts of the country, and by numerous plans he demonstrated what could be done, in small space and with small expenditure, if means were really related to needs Many of his examples were drawn from buildings erected with the help of the Nuffield Provincial Hospitals Trust—which he described as the most powerful instrument of social research and planning that exists in the sphere of the health services These examples included particularly the health centres of Harlow New Town, which he and his associates have lately described, with illustrations, in our columns [1]

In conclusion Dr Taylor spoke of the need, first, for accurate knowledge of the work that has to be done in the building, secondly for creative social planning, so that the demands shall be the least consistent with efficiency, and thirdly, for careful architectural planning inside the strictest possible budget

LOUIS RAPKINE ASSOCIATION

ON the lines of the Horse Shoe Club, which fosters friendship between American, Canadian, and British workers in medicine, the Louis Rapkine Association has been formed for French and British doctors and medical scientists who have held scholarships and bursaries in each others countries The members, grouped into British and French sections, undertake to give what advice and help they can to visitors from the other country, and the plan is that each section shall hold an annual reunion The British section was inaugurated on May 14 at the Ciba Foundation, when Dr Etienne Berthet, director of the International Children's Centre, gave an address entitled Evolution et Tendances de la Medecine Contemporaine

Among those attending the inauguration were Madame Rapkine, widow of the French biochemist after whom the association is named A brief account of Rapkine's life, from his birth in White Russia in 1904 to his death in 1948, shows that he was indeed "a man of exceptional personal qualities who believed ardently in the need for international cooperation in science" Trained at McGill University, he went to France in 1924, and despite privation was already doing important work on cell activity before he was 21 In 1934 he started a committee for academic refugees from Fascist countries, and an international organisation was in prospect when war broke out In 1940 he was in London with a French government mission, and set about helping scientists who might be in danger in the occupied zone of France He arranged in the first instance for them to go to the United States He had to obtain their safe exit, pay their passages, persuade the Americans to give them entry, and maintain them until they could take up the research posts he had found for them Later this work was transferred to the United Kingdom, where the Mission Scientifique Française en Grand Bretagne was established Before this group returned to France in 1945 Rapkine had done much to re establish scientific contacts which had been broken by the war, and he had also persuaded the French government to maintain a permanent scientific office both in England and in the U S A to strengthen the links formed During his time in London, too, he took an active part in the foundation of that unique residential club, the Society for Visiting Scientists "The story of Louis Rapkine" as the brief biography says, "is one of the strength of the individual His integrity and complete disinterestedness gained him the support of the influential, his faith and enthusiasm won over the indifferent and sceptical, and his single minded determination cut through the barriers of officialdom and of red tape in all departments of life"

Further information about the association may be had from Dr G E W Wolstenholme, Ciba Foundation 41 Portland Place, London, W 1, or from Miss A M Vidal Hall Scientific Office, French Embassy, 22, Wilton Crescent, S W 1

---

University of Oxford

On June 2 the honorary degree of D SC was conferred on Prof Ragnar Granit, of Stockholm Dr G W Pickering, the new regius professor of medicine, was incorporated doctor of medicine, as a graduate of the university

The degree of D M was conferred on J C F Poole, and the degree of CH M on Harold Ellis

University of Cambridge

Dr D G Chalmers has been appointed a university assistant pathologist at Addenbrooke's Hospital

University of Manchester

Dr B J Leonard has been appointed demonstrator in pathology

University of Durham

Dr G A Smart, reader in medicine, has been appointed to the professorship of medicine in the Newcastle division of the university

Dr Smart who is 42 years of age was at school at Uppingham and graduated M B from the University of Durham in 1937 and took his M D two years later During the late war, with the rank of squadron leader in the R A F Medical Service he acted as specialist in nutrition surveys In 1948 he was awarded a Commonwealth Fund fellowship Before taking up his present appointment he was lecturer in medicine in the University of Bristol He has published papers on pituitary function and on the rôles of the adrenal cortex in diabetic acidosis

Scottish Food Hygiene Council

The 17 members of this council include Dr G Matthew Fyfe, M O H for Fife, and Dr John Smith, director of the regional laboratory, City Hospital, Aberdeen The chairman of the council is Sir William McNair Snadden

British Tuberculosis Association

The annual conference of this association is to be held in Bristol from June 27 to 30 Further particulars may be had from the administrative secretary of the association, 5 Portland Place, W 1

Royal Medical Benevolent Fund

The annual general meeting of this Fund was held on June 5 when the following honorary officials were re elected president, Lord Webb Johnson, hon treasurer, Mr F A Juler, and hon secretary, Dr R Cove Smith

British Association of Pædiatric Surgeons

This association is to hold a joint meeting with the surgical section of the American Academy of Pediatrics in London, from July 17 to 19, under the presidency of Mr Denis Browne The annual dinner of the association will be held on Thursday, July 19 at 8 P M at the Apothecaries' Hall The scientific meetings are open to non members, and further particulars may be had from the hon secretary, Mr D J Waterston, Hospital for Sick Children, Great Ormond Street, W C 1

CORRIGENDUM *British Institute of Radiology*—In our report of Professor Spiers's presidential address (June 2 p 839), we wrongly included the statement that the ^{40}K body content was now established at about 0 2% of body weight This figure in fact refers to the *total* potassium content of the body

Prof A C Frazer head of the department of medical biochemistry and pharmacology in the University of Birmingham has been elected president of the British Food Manufacturing Industries Research Association

Hospitals Directory for England and Wales 1955—A new edition of this directory has been published this week Copies may be had from H M Stationery Office, price 15s androgens and prolonged treatment with testosterone the patient retained a rather infantile appearance and no moustache developed

Case 2—In childhood lived as a normally developed boy At age of 14 spontaneous start of puberty with deepening of voice and growth of genitalia and pubic hair, but at the same time increasing obesity with feminine distribution of the fat Admitted at age of 18 on this account

On examination general appearance markedly feminine and somewhat infantile Moderate obesity with pronounced feminine fat distribution broad hips and large nates and mammæ On palpation of the fat in mammary region glandular tissue was not felt with certainty Height 172 cm no eunuchoid skeletal proportions Voice somewhat higher than normal muscular strength considerably less than in normal men of the same age Dense growth of pubic hair axillary hair scanty moustache almost absent Penis hypoplastic and very short (39 mm) scrotum well developed Testes very small (diameter about 13 mm.), firm

Hormone excretion per 24 hours total neutral 17 ketosteroids 5·7 mg androsterone 2·2 mg etiocholanolone 1·4 mg gonadotrophins >50 mouse units

Testicular biopsy—Complete hyalinisation of seminiferous tubules Between tubules large dense masses of Leydig cells

Oral and urogenital smears in case 1 showed typical chromatin-positive (“female”) nuclei The sex diagnosis was kindly confirmed by Professor Barr Unfortunately we have not been able to examine epithelial smears from case 2 but several blood smears were obtained These showed—as in case 1—typical “drumsticks” which denotes that the preparations had a female character

These surprising findings must be interpreted as an indication of a sexual “shift” early in fœtal life Grumbach et al[6] have reported various investigations concerning the fœtal sexual development of patients with “gonadal dysgenesis” They concluded that lack of testicular tissue converts the fœtal sexual development in males in a feminine direction It is difficult to explain the reported findings in patients with Klinefelter's syndrome unless one imagines the presence of a hypothetical strong male “inductor” in the early weeks of their embryonic life

We look forward to other reports on nuclear sex in cases of Klinefelter's syndrome At present we do not even know whether chromatin-positive nuclei are invariably present, or whether a minority of the cases show nuclear sex of male type.

SUICIDE AND PHYSICAL TREATMENTS

Sir,—16 deaths by suicide have occurred during the past two years among patients discharged from the mental hospital at which I work All but 1 had received physical treatment of a more or less drastic kind

The 4 female patients had all received electroconvulsive therapy (1 of them leucotomy too) Of the remaining 12 male patients 7 had had E C T 2 had undergone a modified deep narcosis and 2 passed through a three weeks course of modified insulin—up to 80 units

The Registrar General reports an increase in the number of suicides throughout the country from 3447 in 1944 to 5033 in 1954 That is an increase of 1586 deaths by suicide

My own figures show an average of 8 deaths by suicide per annum for 1954 and 1955 If this experience were to be repeated among more than 100 mental hospitals in the country then the increased suicide rate could be substantially accounted for by the psychiatric cases leaving mental hospitals after physical treatment Especially so if as must be remembered the cases came to my notice by casual (though confirmed) report

This letter can only be regarded as a preliminary note to a more searching investigation

NIKETHAMIDE IN RHEUMATOID ARTHRITIS

Sir—During the past eighteen months I have treated 38 successive cases of rheumatoid arthritis with nikethamide and have had 38 cures The patients were all Africans aged 25–60 and were nearly all women. They had had symptoms for between six months and twenty-three years The treatment is very simple—2 ml of nikethamide (‘Coramine’) is given thrice weekly for three or four weeks There have been no relapses so far that I am aware of and the effects are apparently lasting There are no side effects and no contra-indications and improvement often starts with the first injection

2 cases are reported here but the others are just as striking

Case 1—The patient was a woman aged about 55, who had had the disease for twenty-three years When first seen she was sitting huddled in front of her hut knees under her chin spine bent and arms folded in front of her in the position of least discomfort There was pronounced ulnar deviation of the fingers and wrists whose joints were grossly deformed and tender The other joints were not so obviously deformed but were nevertheless painful and tender, and even the spine was involved The joints of the feet had over all about 60% of normal movement and there was progressive deterioration upwards to the hands which had at most 10% The skin over the hands and forearms was atrophic and shiny and that of the face showed the crazed porcelain effect so often seen in these patients

As this was the first case I had treated with nikethamide I gave her daily injections for twenty-one days and thereafter twice weekly for a further three weeks She reached maximum improvement after two weeks At this stage she could place both hands behind her neck for the first time in many years and could close both hands tightly except for the two ring fingers which were the seat of an unyielding ankylosis at their two interphalangeal joints The pain and tenderness had disappeared but the ulnar deviation and a good deal of the deformity persisted The neck had a full range of movement and the knees were greatly improved but there was a little stiffness of the hip joints The skin of the hands and forearms had regained a normal appearance but that of the face was unaltered Formerly a helpless cripple unable even to dress herself she was now able to do most of what a normal woman of her age could do The only treatment apart from the nikethamide was manipulation of the wrists fingers neck and knees because the patient lacked the confidence to move these joints sufficiently herself I have not seen the patient for fifteen months but inquiries a few months ago revealed that she was still well

Case 2—This patient was a man aged 45 He was employed as a labourer by the South African Railways and was referred to me for certification of unfitness because he was so often ill It was found that he had rheumatoid arthritis and had had symptoms for eight years I asked that he be allowed three weeks sick leave to have a course of treatment If he was not cured after this time he would be boarded The worst trouble was in the joints of his shoulder girdle but hands elbows and knees were also involved He had nine injections of nikethamide and went back to work with only 5° less than full extension of the right arm at the shoulder All other movements were full and normal It is nine months since his treatment and he has never been absent from work since nor had any further treatment

Circumstances here in the bush do not permit of adequate investigation of each case and neither radiography nor estimation of the erythrocyte-sedimentation rate has been undertaken Moreover it is quite impossible to persuade Africans to attend for follow-up examinations They would certainly return however if they had a recurrence of symptoms All the patients must come to the dispensary for treatment and for most this involves a walk of several miles each time This may have some bearing on the treatment Nikethamide was found to have no effect on infectious or traumatic arthritis or osteo-arthritis

Without basic research which is impossible here I do not want to discuss any theory But apparently the

CHRONIC PYELONEPHRITIS *

JAN BROD
M D Prague
ASSISTANT PROFESSOR OF MEDICINE, CHARLES UNIVERSITY, DEPUTY DIRECTOR OF THE INSTITUTE FOR CARDIOVASCULAR RESEARCH, PRAGUE KRČ, CZECHOSLOVAKIA

"CHRONIC pyelonephritis" denotes inflammation which has spread to the kidney from an infected renal pelvis The inflammation is interstitial and scars and destroys the surrounding parenchyma in a patchy distribution, and there are great differences in the extent of inflammation and destruction not only between the two kidneys but also between different parts of one and the same kidney The structures affected most seriously by pressure, interference with nutrition, and the toxic by products of inflammation are the tubules, which are atrophic and often cystic and dilated, and often disappear in the inflamed tissue The glomeruli, on the other hand, retain their normal structure much longer, being destroyed only when the inflammation breaks through the wall of Bowman's capsule (the "invasive glomerulitis" [fig 1] of Kimmelstiel and Wilson [1936]) or when the afferent arteriole is damaged by hypertension (the "alterative glomerulitis" of the same workers)

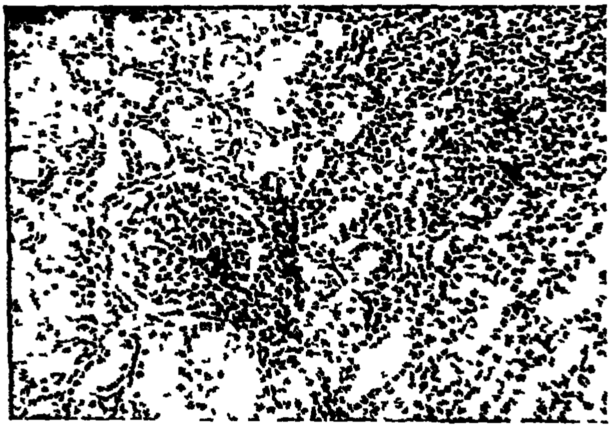

Fig 1—Invasive glomerulitis.

In two thirds of the cases the pyelonephritis is secondary, being a complication of a primary lesion elsewhere in the urinary tract, but in the remaining third the pyelonephritis is primary, there being no obvious lesions in the ureters or in the renal pelves If infection is responsible in these latter cases it must be blood borne Sampson (1903) and other workers, however, have shown that hæmatogenous infection produces pyelonephritis only if the free flow of urine has been disturbed Therefore in the absence of organic obstruction there must be functional interference with the flow of urine

Infection, however, is not indispensable in the pathogenesis of pyelonephritis Simonsen (1953), in his work on the fate of renal transplants, found morphological changes similar to those of chronic pyelonephritis without any evidence of infection, they were probably of allergic origin I do not intend to discuss here the details of the pathogenesis and the paths along which infection and inflammation spread from renal pelvis to kidney Whatever these paths, the result in the kidney is the same

Pyelonephritis has been well known to pathologists for a hundred years but little known to clinicians, and has usually been diagnosed only by urologists as a late complication of renal failure in disease of the urinary tract For decades pathologists have increasingly called attention to pyelonephritis, and some physicians have recognised its importance, especially in hypertension (Butler 1937, Longcope 1937, Weiss and Parker 1939, Pickering and Heptinstall 1953, Langley and Platt 1947, and others)

Raaschou (1948) focused the attention of clinicians and nephrologists on this important, common, and dangerous disease Using clearance techniques he showed that pyelonephritis affects the function of the kidney in rather a specific way He also established that, in Copenhagen, pyelonephritis was the commonest cause of uræmia, being found in 1 in every 14 necropsies (6 3%)

The prevalence of pyelonephritis in our population is almost exactly the same as that found by Raaschou of 1196 necropsies in the pathological department of the Thomayer Hospital, Prague, in two and a half years Horák and Kratochvilová (1955) found chronic pyelonephritis in 74 (6 18%) In 48 (65%) it was a complication of primary lesions of the urinary tract, in 26 (35%) it was a primary lesion without any obvious change elsewhere in the urinary tract Hypertension was a complication in 41 8% of the cases, being commoner in the primary cases (65 3%) than in the secondary (29 1%) A surprisingly high proportion of both primary and secondary cases had escaped clinical recognition—50 of 74 (67 5%)

The seriousness of this lack of clinical recognition of pyelonephritis is obvious from the causes of uræmia in 69 deaths from renal failure in the necropsy material of the same period although chronic pyelonephritis was less common than in Raaschou's (1948) material, it was the commonest renal cause of death accounting for 36 2% of cases of uræmia, whereas glomerulonephritis accounted for 18 8% and vascular nephrosclerosis for 14 5%, leaving 30 5% due to other and far less important causes (renal amyloidosis, polycystic kidneys, acute renal failure, &c)

These pathological data show how important it is to improve the clinical diagnosis of pyelonephritis

Material

I began to be interested in pyelonephritis in 1948, when a patient presented with what appeared to be malignant hypertension and a renal functional pattern which differed from that usually found in malignant nephrosclerosis At necropsy chronic pyelonephritis was found In a report of this case to our cardiological society I suggested that the disturbance of renal function might be specific for pyelonephritis (Brod 1948) In that same year I observed several similar cases, all of which I diagnosed as chronic pyelonephritis on the disturbances of renal function, the diagnosis being confirmed by the pathologist

Since then 132 cases have been diagnosed in this institute as chronic pyelonephritis on clinical grounds The study of this group has yielded data which may contribute to a better understanding of pyelonephritis, and to its better diagnosis by methods within the competence of almost any small general hospital

Our group comprises mainly patients treated as either inpatients or outpatients on the medical side It constitutes, however, only about half the cases of pyelonephritis The other half comes under the care of either urologists or gynæcologists, the clinical picture being primarily either urological or gynæcological

The data which we obtained on renal function in some of these latter cases did not differ materially from those in our medical patients, so perhaps the conclusions reached in our group may also be valid in the surgical cases

Correlation of Clinical Diagnosis with Pathology

Fig 2 shows that, of 22 patients who were diagnosed clinically as having chronic pyelonephritis and underwent either biopsy or necropsy (16 7% of the whole group), the diagnosis was confirmed morphologically in 20 (91% of the 22 patients) Of the 2 patients in whom the diagnosis was not confirmed morphologically, 1 had a thrombosed renal artery, and the other malignant effect of nikethamide is not similar to that of salicylate or cortisone It would be interesting to know whether Europeans and Asiatics respond to nikethamide in the same way as Africans

POTASSIUM-CHLORATE POISONING

SIR,—Dr Davies (May 5) mentions among the effects of potassium chlorate "the effect of the chlorate ion, which denaturates Hb with the production of Heinz bodies, and lyses the erythrocytes"

In my own experiments (incubation mixture 0 8 ml pH 7 0 $M/15$ phosphate buffer, 0 2 ml 1 9% potassium chlorate, and 0 5 ml washed red blood-cells , temperature 37°C) I have found that the decrease of catalase activity appears prior to the denaturation extending over the whole cell I did not observe formation of Heinz bodies By the 60th minute of incubation catalase activity had decreased about 50%, and by the 120th minute 75% Probably the sensitivity of catalase is higher against the chlorate ion than that of other cell-proteins, and even in-vivo Heinz body formation is not due to the direct effect of the chlorate ion, but indirectly to the catalase inhibition

GENESIS OF TROPICAL ANÆMIAS

SIR,—Dr Foy and Dr Kondi, in their preliminary communication of April 14 on iron losses in the genesis of tropical anæmias, appear to have modified some of their previous findings Thus, in 1952 [1] they classified the anæmias of Africans into "four well defined groups" iron deficiency anæmia, nutritional megaloblastic anæmia, sickle cell anæmia, and "splenic hæmolytic anæmia" Comprehensive data were published on the first two groups These could be clearly separated by examination of mean diameter, mean corpuscular volume, and mean corpuscular hæmoglobin concentration, and a consideration of the bone marrow in terms of megaloblasts and pathological "stab cells" Deficiencies were usually single There was, in their opinion, no overlap between the groups, which were distinct and identical with those described in other parts of the world I had always hoped that further work might reconcile apparent differences of opinion, since they were at that time unable to recognise or study anæmia due to protein malnutrition or liver damage, subjects not mentioned in their article

In an article [2] published independently by me earlier this year these divergences of opinion appear to have been reduced Within the last eight years a definite place has been accorded to the anæmia of protein malnutrition [3–6] and to that of chronic liver damage [7–10] It is not generally recognised that the latter usually produces moderate anæmia in which the red cells are macrocytic in respect of the mean diameter, and there is often an accompanying mild reticulocytosis In earlier studies of mine [11] the disturbances of protein metabolism due to diet (kwashiorkor), hookworm disease, and chronic liver damage were not clearly differentiated it was merely noted that some anæmias responded to iron and some to whole liver, but some apparently required both to complete the cure The latter anæmia I ventured to call "dimorphic anæmia" When at the end of the war, liver extracts became available it became apparent in Uganda that more cases responded to whole liver than to liver extracts This is probably because the former is rich in protein, and these cases are now treated with skim milk protein

It is now clear that Dr Foy and Dr Kondi also admit the effect of protein malnutrition, although it is not clear in any of their published observations what they consider are the morphological characteristics of the resultant anæmia when it occurs unassociated with infection or iron deficiency However, they acknowledge that microcytic hypochromic anæmia as seen in the tropics may be due to "multiple deficiencies and "the failure of some cases to respond to iron alone and the appearance of other deficiencies during iron treatment indicate the complexity of the problem" They found that some of these cases required extra protein and/or the pernicious anæmia group of hæmopoietic factors to complete cure Recent work by Tasker [12] suggests that these two types of deficiency are sometimes associated in Malaya It seems that most workers now accept the fact that anæmia in the tropics has often more than one deficiency in Uganda usually iron and protein are involved, occasionally one of the P A factors the latter is more common in Kenya and among Indians

While stressing the deficiency approach to anæmia, I must register a protest that *severe* anæmia in most tropical regions is usually due more to a tropical infection than a deficiency In young children in Uganda it is largely due to malaria, slightly older children, poor immigrant labourers, and destitute women may all suffer from "hookworm anæmia" Small blood clots can be seen in the intestine at necropsy, and it has been repeatedly demonstrated [13] and confirmed by recent work that cases cannot be cured completely by oral iron or massive injections (4 g) of intramuscular iron, large protein supplements, and large injections of vitamin B_{12} After an initial rise to 6–10 g per 100 ml , the hæmoglobin level remains stationary, in spite of a high reticulocytosis, until repeated deworming reduces the load Immediately this occurs the blood count leaps upwards while at the same time the reticulocyte count falls

It is quite true and has been known for a long time that there is no correlation in any community between hookworm loads and the hæmoglobin level, yet occasionally for reasons not understood one person becomes severely anæmic This, however, does not explain the widespread but moderate anæmia which is so prevalent in tropical communities Dr Foy and Dr Kondi suggest this may be due to iron losses in the sweat As a preliminary question one might ask whether this widespread but mild anæmia is cured by giving oral, intramuscular, or intravenous iron In my experience after an initial improvement, it is seldom possible to cure this moderate tropical anæmia, or to produce a "normal" blood count, especially high red cell counts, even after giving much iron and protein Whether this reflects, as I suggest, widespread irreversible liver damage is uncertain

One of the great difficulties in reaching agreement with other hæmatologists is terminology Thus when Dr Foy and Dr Kondi speak about a "dyshæmopoietic" anæmia or bone marrow they refer exclusively to one reflecting a deficiency of one or other of the P A group of hæmopoietic factors No other hæmatologists, as far as I am aware, restrict the term thus Surely a dyshæmopoietic anæmia occurs whenever there is a deficiency present, and there are also those due to deficiency of iron, ascorbic acid, thyroid extract, calories, protein, and other factors Many of these have distinctive morphological changes in the marrow and peripheral blood Another basic assumption of Dr Foy and Dr Kondi, substantiated by much of the literature, is that pathological giant "stab cells" even by themselves are almost proof of one or other of the deficiencies of the P A group (a "dyshæmopoietic" marrow, as they call it) While this is usually accepted due weight must be given to the opinion of others [14–17] that giant "stab-cells" may occasionally occur in the marrow smears of iron deficiency anæmia in Europe and America The truth is that few have studied the marrow in iron deficiency dyshæmopoietic anæmia or waited to see whether iron by itself in the tropics increased

nephrosclerosis in a kidney displaced into the pelvis without obvious chronic pyelonephritis

The clinical and the pathological diagnosis agreed in 49 (91%) of 54 cases of chronic glomerulonephritis and in all 16 cases of vascular nephrosclerosis

These satisfactory results allow us to draw conclusions from our clinical group with the same certainty as from other diseases diagnosed clinically

Diagnosis

History

A very thorough history of present and past symptoms was first obtained

44 7% of the patients complained of either present or past *frequency and dysuria* (symptoms of inflammation of the urinary tract), and 64 4% of either present or past *pain* in the loins, this was of the severe colicky type in those with a history of lithiasis, but more frequently the pain was dull In 35 6% of the cases, however, there was no pain This shows that interstitial inflammation in the kidney is painless, and that any *pain present* must be due to another cause—probably spread of the inflammation to structures in the neighbourhood of the renal pelvis, or irregular contraction of the ureters

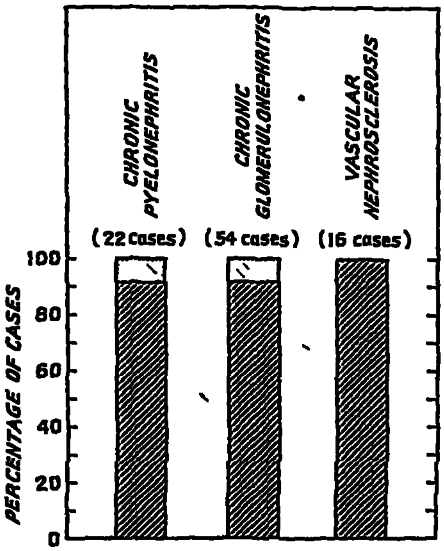

Fig 2—Incidence of agreement (hatched areas) of clinical and pathological diagnoses

Clinical Examination

Routine physical examination included that of the genitalia, palpation per rectum, and retinoscopy

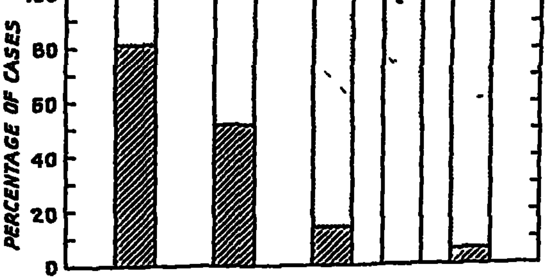

Fig 3—Incidence of pathogenic bacteria (hatched areas)

Pyelonephritis and glomerulonephritis	13 978<0 001
Pyelonephritis and healthy	38 412<0 001
Glomerulonephritis and healthy	18 038<0 001

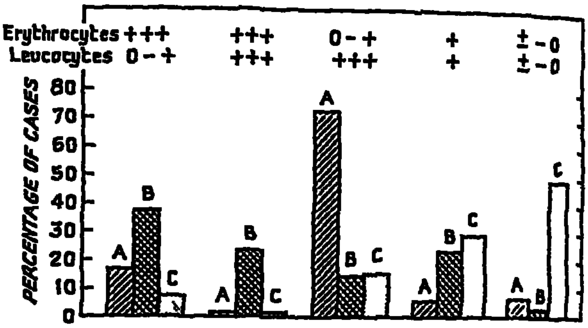

Fig 4—Cells in urinary deposit A chronic pyelonephritis, B, chronic glomerulonephritis, C, nephrosclerosis

Pyrexia, rarely exceeding 100 4°F, was found in only 25 0% of the patients

From a quarter to a third of them complained of vague *constitutional symptoms*—e g, lassitude, malaise, headache, anorexia, nausea, dyspepsia, and breathlessness on exertion In about two-thirds of the patients all these symptoms could be correlated with late renal failure hypertension, or pyrexia, but in about a third of them no such explanation was forthcoming, and the symptom had to be attributed to the focal inflammation in the kidney

17 25% of all the patients and 40 0% of those with primary pyelonephritis were referred because of a chance discovery of proteinuria, 8 33% because of high blood pressure, and 1 5% because of thirst and polyuria, but, when questioned specifically, 21 9% admitted to thirst and 11 4% to polyuria

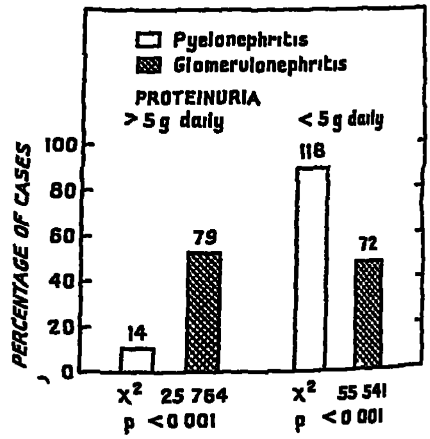

Fig 5—Proteinuria.

Routine physical examination yields practically no further information, unless pathological changes in the pelvis or in the genitalia, hypertension, or signs due to renal failure are found Although 23 patients reported having had œdema, it could be explained by extrarenal causes in 21 of them

Laboratory Investigations

Little is gained from routine laboratory examinations including chest radiography, electrocardiography, estimation of the erythrocyte sedimentation rate (E S R), blood count, and estimation of non protein nitrogen plasma proteins, and cholesterol

A rise in the E S R, a fall in the red cell count, and a decrease in the amount of *hæmoglobin* correlate best with renal failure, poorly with pyrexia, and irregularly with the inflammation in the kidneys A slight increase in the white cell count was observed in 25% of the patients with pyrexia

Thus, the history, clinical examination, and ordinary laboratory tests in pyelonephritis without renal failure afford, at most, only information about the presence or absence of inflammation in the urinary tract, without the blood-count until it became *quite* normal The disappearance of pathological stab cells after treatment by one of the P A group of substances is very suggestive

In propounding the term "dimorphic anæmia," [11] I wished to draw attention to a puzzle anæmia in the tropics was not always due either to iron deficiency or to nutritional megaloblastic anæmia There was overlap, there was confusion I must have defined the term poorly, for many who subsequently used the term gave it a different meaning I have ceased to use it, for it incorrectly and inadequately oversimplified the problem Much anæmia in the tropics is "polymorphic" It is still a puzzle, although many of the pieces are beginning to fit together

It is to be hoped that Dr Foy and Dr Kondi will continue their work on iron losses in the skin and sweat of those who live in tropical countries For my part I regret if any of my writing suggested there was some deep mystery about the tropical anæmias Much which appeared mysterious to me twenty years ago now appears explicable in terms of iron deficiency, megaloblastic deficiency, protein malnutrition, and liver disease, in which I must now have performed over 500 biopsies Much remains to be done for instance why do iron-deficiency anæmias in the tropics *rapidly* become macrocytic when iron therapy causes a reticulocytosis ? I have been unable to find any hæmatologist in temperate regions who has noticed this change, and others record data which deny that it occurs [18] I suggest this is due to intercurrent liver damage and protein malnutrition, present usually in the tropics but seldom in temperate regions

Mulago Hospital,
Kampala Uganda

H C TROWELL

SIR,—We have some evidence to indicate that, contrary to the opinion of Dr Foy and Dr Kondi, the rôle of hookworm in the genesis of some tropical anæmias is probably a paramount one We have "marked" the red blood cells of 22 subjects with hookworm infestation, with and without anæmia, and studied radioactivity in the fæces and in the blood

Fæces were collected in three four day periods, and radio activity was compared with that present in the blood at the beginning of each fæcal collection The same study was repeated after tetrachloroethylene treatment and recovery of the hookworm in the fæces in 15 patients We were thus able to show that each hookworm is responsible for the loss of an average of 4 19 × 10^{-2} ml per day of blood, with extremes of 0 98 to 15 53 × 10^{-2} ml per day

Generally, blood-loss per hookworm was relatively larger in patients with very low hæmoglobin, and diminished as the patients' hæmoglobin increased, either through iron therapy or after transfusions None of the group of 8 patients with light infestations (less than 200 hookworms) had a hæmoglobin below 10 g per 100 ml Of the 14 patients with severe infestations (more than 400 hookworms), 11 had hæmoglobin values below 8 g per 100 ml However, one of the latter patients, with 509 hookworms, had a hæmoglobin of 15 8 g per 100 ml, and lost only on the average 6 08 ml of blood per day (that is, 1 18 × 10^{-2} ml per hookworm per day) His diet, as contrasted to that of most of the other patients, was excellent, being both fisherman and farmer, he ate fish, milk, and vegetables daily

It is of course our impression that loss of blood is not the only factor involved, and in the last case, diet was obviously important On the other hand, it is difficult to dismiss as unimportant losses of blood which may go up to 100 or 200 ml per day Eventually the development of anæmia will depend mostly upon a balance of what comes in (including iron, protein, &c) and what goes out of the patient's body Until the various factors involved are submitted to quantitative evaluation, the final word on this problem will not be forthcoming

In preliminary studies, we have been able to show in humans that chromium tagged to red blood cells introduced into the duodenum is recovered in the fæces almost quantitatively, and that chromium derived from the destruction of circulating red cells is excreted almost entirely by way of the urine These facts strengthen the theoretical validity of our views

Somewhat similar but more limited studies have been reported by Gerritsen et al ,[1] who used radio iron, and determined, in 3 hookworm-infested patients, that the daily blood loss per hookworm was 2 6, 22, and 5 3 × 10^{-2} ml per day respectively

MARCEL ROCHE
Director

DIAGNOSIS OF THYROTOXICOSIS

SIR,—Although the diagnosis and assessment of thyrotoxicosis can usually be made on clinical grounds alone, there is still a certain number of patients in whom the diagnosis remains in doubt In some, the clinical picture is suggestive of thyrotoxicosis without obvious thyroid enlargement, whilst others have a presumed non-toxic goitre with an associated anxiety state Further, unexplained auricular fibrillation or congestive cardiac failure may raise the possibility of "masked" thyrotoxicosis though other evidence of overactivity of the thyroid gland may be lacking

At present tests of radioactive iodine uptake can be performed only in a limited number of centres We therefore feel that more use could be made of estimations of the serum creatine level, in combination with an accurate measurement of the sleeping pulse rate, as a screening test in all doubtful cases of thyrotoxicosis

Serum creatine

Griffiths [2] has shown that a normal fasting serum creatine level of less than 0 6 mg per 100 ml in both men and women excludes all but the mildest, relatively symptomless, cases of hyperthyroidism, and differentiates the anxiety states from true thyroid disorders He concludes that patients with suggestive symptoms and raised serum creatine levels should be regarded as thyrotoxic and treated accordingly, even if the basal metabolic rate is normal

In our small series, serum creatine levels, not necessarily fasting, were estimated in 19 patients admitted with clinical evidence of thyrotoxicosis under the care of the consultant staff at the Royal Devon and Exeter Hospital Using the method described by Peters,[3] the accepted maximal normal value of 0 6 mg per 100 ml was exceeded in every case studied In the more severe cases, the serum creatine levels ranged from 1 0 to 2 3 mg per 100 ml Within a few days of starting medical treatment with propylthiouracil or carbimazole, or alternatively following subtotal thyroidectomy, the levels had frequently fallen to within normal limits In every case normal values were obtained before the end of the sixth week In fact it would appear that the maintenance dose of anti thyroid drugs can be controlled satisfactorily using this test 6 patients with non toxic nodular goitres, confirmed on histological examination, had normal serum creatine levels prior to operation

It should, however, be remembered that the serum creatine is raised in other conditions, associated with disordered muscle metabolism For example, one of us (D M) has frequently found raised levels in patients with rheumatoid arthritis

Sleeping Pulse rate

A raised sleeping pulse rate is one of the classical signs of thyrotoxicosis Accurate recordings are, however, notoriously difficult to obtain without waking the patient We have used the sensitive pulse indicator described by Simpson [4] for this purpose and thereby obtained accurate sleeping pulse rates throughout the night The instrument is simple to construct and can easily be operated by the nursing staff It utilises a small carbon throat microphone which is strapped to the pulp of the great toe with 'Sellotape' Light flex, several feet long, connects the microphone to the instrument placed on the locating it when present To do this it is necessary to study the urine and renal function This study consisted in analysis of the urine, an Addis count, a twenty four-hour curve of the glomerular filtration-rate (assessed by endogenous creatinine clearance), concentration and dilution tests, intravenous pyelography, and, when necessary, urological examination, including ascending pyelography and estimation of separate concentration indices ($\frac{U}{P}$ ratio) of endogenous creatinine

Bacteriology

The causal micro organisms can often be cultured from the urine Fig 3 shows that pathogens—i e, bacteria other than *Staphylococcus albus*—were found in the urine of 81% of the patients, irrespective of sex and of whether the pyelonephritis was primary or secondary This is in striking contrast with the findings in 30 healthy people, in whom pathogens were present in the urine of only 6% Moreover in healthy females, from whom bladder urine was obtained through a catheter, pathogens were not found at all, whereas in healthy men, who provided mid stream specimens, pathogens were found in 14%, but never any *Escherichia coli* The pathogens in male urine obviously came from the urethra

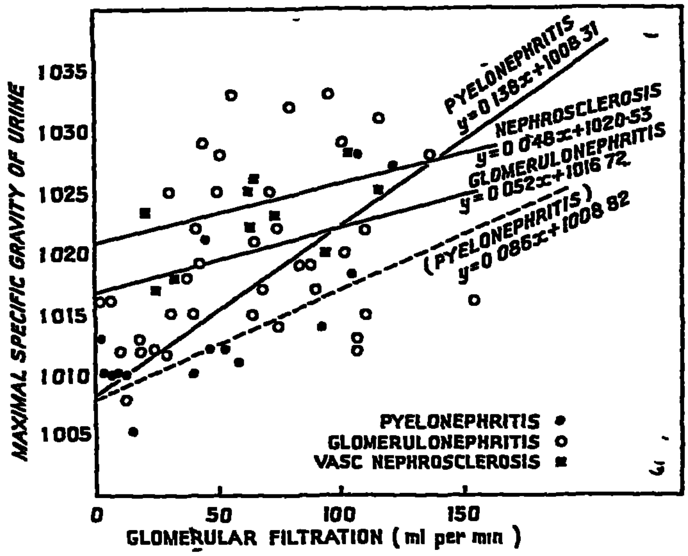

Fig 8—Correlation of glomerular filtration-rate and maximal specific gravity of urine If 2 cases of chronic pyelonephritis with unusually high powers of concentrating urine are excluded regression line is as shown by interrupted line

In chronic glomerulonephritis there was an unexplained and relatively high prevalence of pathogens in the urine (no sex difference was found in this disease), but the prevalence of infected urine in chronic pyelonephritis was significantly higher Among these organisms *Esch. coli* was the most frequent (45%) *Staph aureus* (28%) and *Streptococcus fæcalis* (27%) came next, while proteus (3 27%) and *Pseudomonas aeruginosa* (4 26%) were found in only a few of our patients—no doubt because there were no heavily infected urological cases among them

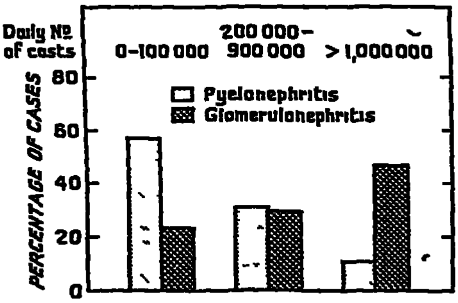

Fig 6—Casts in urinary deposit.

Addis Count

The second most important sign of inflammation of the urinary tract, simultaneously indicating its severity, is the quantity of leucocytes in the urine, estimated by the Addis count Leucocytes formed the greater part of the urinary deposit in 76% of the patients (fig 4) In glomerulonephritis and vascular nephrosclerosis this happened in only about 14% of cases

In 16% of the patients with chronic pyelonephritis there were more erythrocytes than leucocytes in the urinary deposit Most of these patients had a history of either cystopyelitis or lithiasis, and the bleeding was obviously due either to hyperæmia or to trauma of the mucosa of the urinary tract In glomerulonephritis, on the other hand, this happened in more than a third of the cases, and in vascular nephrosclerosis in only 7%

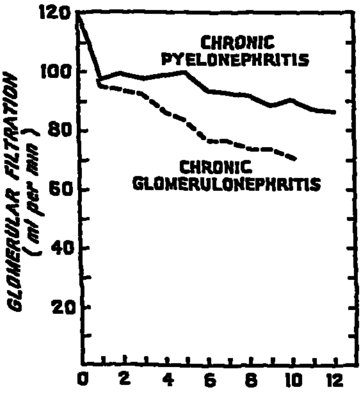

Fig 7—Changes in glomerular filtration-rate

Large and equal increases of both erythrocytes and leucocytes argue against chronic pyelonephritis and in favour of glomerulonephritis The most typical finding in vascular nephrosclerosis was a very small urinary deposit with very slight and equal increases of both erythrocytes and leucocytes

With only this indirect and direct evidence of infection and inflammation we could not, of course, localise the inflammation Only if we find signs of functional renal damage due to the spread of inflammation to renal interstitial tissue, and to damage and destruction of the surrounding structures, can we be reasonably certain about our diagnosis of pyelonephritis

Proteinuria

The late destruction of the glomeruli in pyelonephritis has been emphasised, but the presence of a severe toxic process in the immediate neighbourhood of the glomeruli will damage their finest structures (the walls of the capillaries) so much that they will leak protein, and proteinuria will ensue Contrary to what happens in glomerulonephritis, which attacks the glomeruli primarily, the quantity of protein in the urine in pyelonephritis rarely exceeds 5 g daily (fig 5)

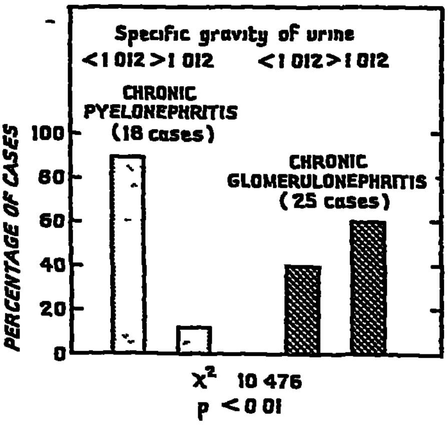

Fig 9—Incidence of inability to concentrate urine to sp gr >1·012, with glomerular filtration rate <30 ml per min

Protein in urine in the tubules and degenerated cells of the tubules yields material from which ca patient's bed table We have found that patients soon get used to this and sleep is not disturbed

We have placed further emphasis on these established methods in the hope that they may assist others in the differential diagnosis of thyrotoxicosis and anxiety states We suggest that serum creatine levels can be estimated on such patients during their first outpatient attendance Those with raised serum creatine levels can then be admitted to hospital for a few nights so that an accurate recording of the sleeping pulse-rate can be made Further confirmation of overactivity of the thyroid gland will be provided if a definite fall in serum creatine levels and sleeping pulse rate occurs after the administration of Lugol's iodine for three weeks

SALMONELLA OSTEOMYELITIS

SIR,—The article by Dr White and Dr Meynell (April 7), in which they describe a case of paratyphoid-C osteomyelitis, prompts us to comment on a particular aspect of salmonella osteomyelitis which has so far not been adequately considered

They state that their patient is a Jamaican, which, to our mind, means that he is, to some degree, of Negro descent If this is true, it is a pity that the patient has not been examined for the presence of one of the varieties of sickle-cell disease

All observers have stressed the utmost rarity of salmonella infections of the bones This is less true in countries where sickle cell anæmia is prominent At the native hospital of Leopoldville we have observed in less than two years 5 cases of salmonella osteitis, all occurring in infants suffering from sickle cell anæmia [1] This is not a pure coincidence in the available literature we found 8 further cases of this association and recently we came across a 9th published case [2] In one of these publications, the existence of sickle cell disease was apparently not suspected by the author, but the hæmatological data of the patient could hardly fit better with this diagnosis [3]

One of us,[4] reviewing the epidemiology of salmonellosis in the Belgian Congo, referred to 14 salmonella cultures, all isolated from osteomyelitis in Negroes with sickle cell anæmia

These facts seem to suggest that the pathogenetic relationship between the two conditions is very close, and any description of salmonella osteomyelitis in a Negro is incomplete when it gives no information on the presence or absence of sickle cells

In the data given by Dr White and Dr Meynell, the patient's hæmoglobin value is too high for the diagnosis of homozygous sickle-cell anæmia, it is however perfectly compatible with sickle cell/hemoglobin C disease, a hæmoglobinopathy which is known for its ability to provoke bone changes Recently, we reported a case of this disease, with long standing suppuration of one hip [5] Unhappily, the pus was not examined bacteriologically

Provincial Laboratory
Luluaburg, Belgian Congo — J VANDEPITTE

Institut de Medecine Tropicale
Princesse Astrid
Leopoldville Belgian Congo — E VAN OYE

SIR,—The article by Dr White and Dr Meynell was very interesting to us here I wish, however, to draw attention to some inaccuracies

Dr White and Dr Meynell reported that " in the West Indies by far the commonest type of salmonella infection is paratyphoid C ", actually, paratyphoid C is rare and the commonest type of salmonella infection is *S typhi*

They also state that 584 cases of paratyphoid were notified in Jamaica in 1952 The W H O report to which they refer gives this figure under the heading " typhoid and paratyphoid fevers cases ", in actual fact, all 584 cases were typhoid fever, and none were paratyphoid

Only a few months ago we diagnosed our first case of paratyphoid C in Jamaica, and this has attracted so much interest that we are publishing the case shortly

USE OF VITAMIN K IN THE NEWBORN

SIR,—We would like to draw attention to the possible dangers of overdosage with water-soluble vitamin K analogues, when administered parenterally, especially in premature babies

Until recently, it had been thought that vitamin K was entirely non-toxic and might safely be given repeatedly in doses of 10 mg , but recent investigations[1] suggest that in premature babies these doses may lead to the development of kernicterus

There is good evidence that an intramuscular injection of 0 5–1 mg (e g , menaphthone *B.P C*) is more than adequate for the prophylaxis of hæmorrhagic disease of the newborn, due to hypoprothrombinæmia [2] In cases of established hæmorrhagic disease of the newborn due to this cause a dose of 1–2 mg should suffice to restore the plasma-prothrombin to normal levels

PHENYLBUTAZONE IN THE TREATMENT OF PROLAPSED INTERVERTEBRAL DISC

SIR,—I should like to draw attention to the remarkable effect of phenylbutazone in cases of herniated intervertebral disc

In starting this treatment rather over a year ago, I thought that the drug might have an anti inflammatory action at the nerve root, and so diminish the pain of the condition, but so constant has its effect proved in relieving the pain and reducing the physical signs (e g , straight leg raising and areas of altered cutaneous sensitivity) that I now believe that it exerts a direct action on the disc itself, possibly by altering its fluid content differentially as between the annulus fibrosus and the nucleus pulposus In fact, I believe that it performs a " medical manipulation "

Now that I have treated well over 50 cases of disc hernia (cervical, thoracic, and lumbar) with an estimated 90% success rate, I feel the time has come to make known the method so that someone better qualified than myself can produce a properly controlled series, with some research into the mode of action of this extraordinary drug I have been able to find only one report of its successful use in this condition [3]

The dosage I employ is 200 mg three times a day for two days, and then twice a day for two days, making a total of 2 g There is no point in prolonging the administration of this potentially dangerous drug beyond that, since, if it is going to work, it produces dramatic relief in the first thirty six to forty hours, but it has very little effect on the lesser discomfort and stiffness of the healing phase If the condition is not cured in

be formed. It is therefore surprising to find that the number of urinary casts in chronic pyelonephritis is much smaller than that in glomerulonephritis, seldom being more than 1,000,000 a day (fig 6); more than 2,000,000 a day was quite exceptional. The reason for this difference between the two diseases is not clear.

Glomerular Filtration

The changes of glomerular filtration over several years in pyelonephritis and in glomerulonephritis are shown in fig 7.

Fig 7 was constructed on the assumptions that (1) before the start of their disease, all the patients had a normal average glomerular filtration rate of 120 ml. a minute; (2) glomerular filtration decreased regularly from this rate to that found on our first examination; and (3) it continued to decrease regularly from then to subsequent examinations in our laboratory. Data for the intervening years were interpolated. Although the assumptions are unwarranted, the individual deviations from the regular course are certainly in both directions and cancel each other.

A greater obstacle distorting the result is the difficulty of establishing the time of onset of pyelonephritis. The onset was assumed to coincide with the first symptoms; this was almost certainly wrong in most cases and tended to make the course of the disease appear shorter than it was and to give the graph a steeper downward trend. We have to bear this in mind when analysing the diagram.

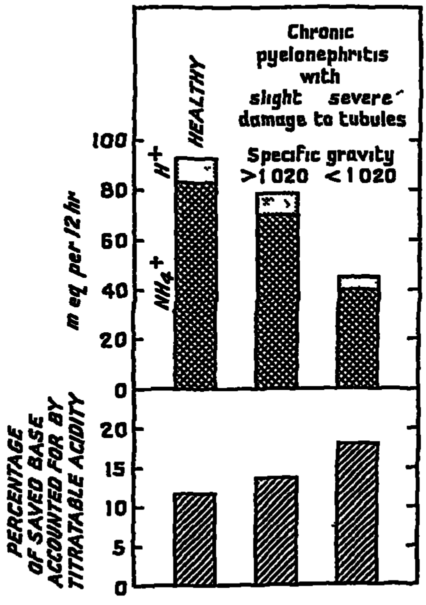

Fig 11—Changes in base-saving in chronic pyelonephritis

The diagram, however, shows clearly that in chronic pyelonephritis glomerular filtration is gradually decreased, but not so fast as in glomerulonephritis. This is in good agreement with the anatomical facts.

Function of Tubules

Grave damage is done to the tubules from the onset of pyelonephritis and disturbs their function. Many nephrons become passive channels which have more or less lost the power of fine differential reabsorption and active excretion.

Little work has been done in our laboratory on the functions of the proximal tubules in pyelonephritis, so I cannot add to the findings of Raaschou (1948). These functions can only be assessed by rather tedious techniques requiring well equipped and well staffed laboratories.

The distal tubules are also damaged from the onset. These tubules form the section of the nephron which, according to current views, reacts sensitively to changes of the blood level of the antidiuretic hormone. By excreting urine of a higher or lower osmolarity than that of the extracellular fluid the distal tubules regulate changes of osmotic pressure (and possibly of volume) of the *milieu interieur*. Also, by exchanging sodium (which accompanies acid radicals in the extracellular fluid and glomerular filtrate) for hydrogen, potassium, and ammonia ions, they help to regulate the acid base balance of the *milieu interieur*.

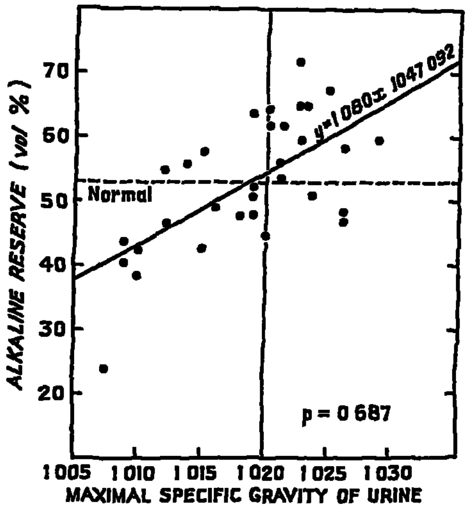

Fig 12—Correlation of maximal sp gr of urine and alkaline reserve

Functional disturbances of the distal tubules can be found in the earliest stages of chronic pyelonephritis by methods practised in most general hospitals. Thus, in almost every case of acute pyelitis, or even transient obstruction of the urinary tract, there is protracted impairment of the concentrating ability of the kidneys. It was this loss of concentrating power, quite out of proportion to the degree of impairment of the glomerular filtration-rate, that brought our attention to this particular disturbance of function.

The dissociation between the reduction of glomerular filtration and the concentrating ability was one of the

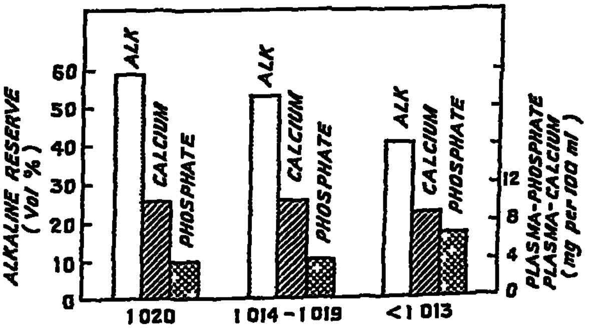

Fig 13—Correlation of maximal sp gr of urine and alkaline reserve plasma-calcium, and plasma phosphate levels

the first four days, phenylbutazone must be abandoned and recourse had to bed rest or other remedies If it is cured, prolonged administration of phenylbutazone will not prevent a relapse, but it will cure such a relapse if exhibited again after an interval It is not necessary to prescribe rest at all in this treatment if the pain is really severe the patient will have to rest whether advised to or not, but lesser degrees of pain are equally well relieved if he carries on with his normal work, and in fact I believe this course is preferable, since it partly prevents stiffness and weakness during convalescence

If anyone is sufficiently convinced by my findings to want to put this treatment to the test, I should be delighted to afford him any help in my power

THE WELFARE OF SPASTICS

SIR,—I was naturally very interested in your annotation of May 5 Because of your suggestion that the National Spastics Society may have ignored the need for "plodding and dispassionate scientific study," I would like to refer to what has for obvious reasons been a little known aspect of our work—research

The Society is setting aside £45,000 for a five year scheme of medical research and has recently allocated £25,000 towards this sum The project is being conducted by Dr Paul E Polani, in collaboration with the Society's medical research committee, and is the most far ranging investigation, prospectively and retrospectively of the ætiological and clinical aspects of infantile cerebral palsies Particular regard is being paid to the association and effects of prematurity and infantile cerebral palsies, and close collaboration is to be maintained with maternity centres It is hoped by this means to procure new evidence on the causation of cerebral palsy

This is the most substantial of the projects comprised in the Society's medical research programme, which however, embraces three other investigations of immediate importance

In Bristol the Society is sponsoring the scientific study of cerebral palsy by a team under Prof A V Neale professor *of child health*

In the sphere of psychology and education a subcommittee is investigating intellectual assessment of those suffering from cerebral palsy

The society is also sponsoring a fourth research project an investigation of intelligence levels at St Margaret's School, Croydon, forming part of the study of the background of cerebral palsy

At this stage it would be wrong to add any more, but I trust the above will suffice to show that the N S S has a well defined policy for tackling this problem

I D DAWSON SHEPHERD
Chairman
London W 1 National Spastics Society

5-HYDROXYINDOLE ACETIC ACID IN URINE

SIR,—The quantitative estimation of the urinary output of 5 hydroxyindole acetic acid has been suggested as the method of choice for a comprehensive evaluation of the general metabolism of 5-hydroxytryptamine under normal, experimental, and pathological conditions

Without precautions to preserve the acidity of the urine—particularly twenty-four-hour specimens—results will not be reliable and comparable This is especially important in cases where the daily excretion of 5 hydroxyindole acetic acid is low, as in some diseases of the blood and liver—e g, Werlhof's disease and other thrombocytopenic diseases[1]

5 hydroxyindole acetic acid is rather unstable to both light and air and in alkaline solution, owing to the presence of a phenolic and an indole group This feature could also explain the red colour of the urine in some patients with an intestinal carcinoid with metastases, where the urinary output of 5-hydroxyindole acetic acid is greatly increased Therefore, when urine is being continuously collected it is absolutely necessary to collect all samples in a dark bottle, which should contain a small quantity of concentrated hydrochloric acid, and if possible the bottle containing the urine should be stored in a refrigerator The addition of the acid to the urine maintains it at the correct acidity (pH 4·0) for the subsequent purification, extraction, and estimation

Department of Obstetrics
and Gynæcology
University of Edinburgh **F J SCANDRETT**

OXYGEN FOR EMPHYSEMATOUS PATIENTS

SIR,—The treatment of emphysematous patients with incapacitating dyspnœa is disappointing, but now, thanks to Dr Cotes and Dr Gilson, whose article appeared last week, domiciliary oxygen therapy is a possibility I eagerly await the results of extended trials and improved apparatus I hope that in their further studies they will be able to estimate the oxygen of the arterial blood by the manometric Van Slyke method, since I have found that the oximeter is quite inaccurate with oxygen saturations of less than 80% It would also be interesting to know the partial pressure of carbon dioxide in the arterial blood in these patients

In regard to their remarks about addiction to oxygen, I do not think there is any great danger since in hospital practice I have had only 1 such case in 5 years, during which I have treated many patients suffering from chronic respiratory insufficiency for long periods with oxygen

I do not want to appear pessimistic, but it is well to remember that one must always be cautious in assessing results, since it is well known that, in emphysema, any form of treatment is liable to produce temporary benefit

Chase Farm Hospital
Enfield Middx **THOMAS SIMPSON**

TUBAL OCCLUSION

SIR,—Twenty-three years ago in Germany there arose a man who postulated that if you say a thing loud enough and often enough, eventually it will be accepted as a fact About the same time a far greater man (Winston Churchill) said at the Royal College of Physicians "The longer you can look back the further you can see forward"

The reason I write thus is that the statistics of a certain hospital have been so often copied, reiterated, and repeated that there is some chance of their being generally accepted I refer to the statement that among patients attending infertility clinics who are found to have blocked tubes, spasm, irritability, anæsthesia, nerves, or even frailty in deductions and methods, are the causes of tubal occlusion in all but 6–7% of cases

There is danger in such a doctrine, for thirty years' clinical experience of hysterography and carbon dioxide insufflation, together with the published figures of three continents, show that, except in Australia, tuberculosis alone accounts for 5–6% of all occlusions Moreover, if the records of infertility clinics are carefully dissected, it will be found that not less than 8–10% of tubal blockage is due to gonorrhœal, pneumococcal, staphylococcal, or *Escherichia coli* infections—to say nothing of endometriosis and those particularly interesting types of complete cornual occlusion where, owing to streptococcal infection of secundines (often following criminal or induced abortion), it will be found that the outer two-thirds of the oviduct in over 80% of cases remains absolutely healthy in its mucous membrane and musculature, and therefore can very readily be used for tubo uterine implantation

To dismiss tubal occlusion airily is hurtful to the community as well as to those who are working, or have worked, in the great cities of the world, for although plastic operative repair can do little for the majority of the first types mentioned it has proven, in capable hands, here and in Paris, to give a 38% success rate from the point of view of subsequent full-term pregnancy, in those young women who have had the misfortune

---

[1] Bigelow, F S *J clin Invest* 1953 32 [illegible]

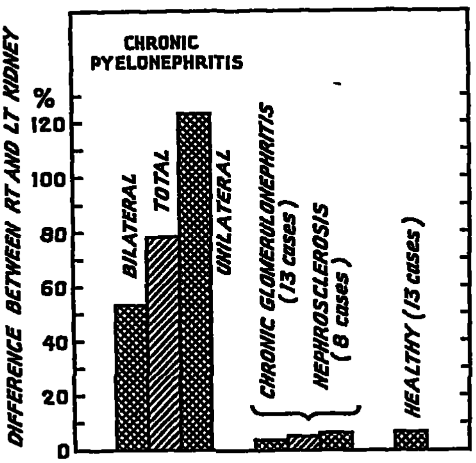

Fig 14—Comparison of concentrating powers of right and left kidneys

main criteria of the clinical diagnosis of chronic pyelonephritis It was therefore necessary to verify the validity of this criterion in 20 cases in which the clinical diagnosis was confirmed by either biopsy or necropsy The findings were compared with those in 49 cases of chronic glomerulonephritis and 16 of vascular nephrosclerosis similarly confirmed (fig 8)

In fig 8 the regression line correlating glomerular filtration with maximal concentrating ability is lower in chronic pyelonephritis than in glomerulonephritis, which gives a lower regression line than does vascular nephrosclerosis This fact supports our previous conclusion that, at all stages of reduction of the glomerular filtration-rate, the impairment of concentrating ability is more severe in chronic pyelonephritis than in chronic glomerulonephritis It also confirms that the loss of function of the distal tubules in vascular nephrosclerosis is gradual and late

Closer inspection of fig 8 reveals another theoretically interesting and clinically important feature of the isosthenuria of pyelonephritis In patients whose glomerular-filtration-rate has fallen below 30 ml a minute the specific gravity of the urine is less than 1 012 (sometimes less than 1 010) more often in pyelonephritis than in chronic glomerulonephritis This is still more obvious in fig 9 Only 10 of 25 patients (40%) with chronic glomerulonephritis, with isosthenuria, and such low average glomerular filtration rates, excreted urine of maximal specific gravity less than 1 012, whereas 16 of 18 patients (89%) with chronic pyelonephritis with a similar reduction of the glomerular filtration rate excreted urine of so low a specific gravity This difference explains why patients with advanced chronic pyelonephritis had more severe polyuria than had patients with chronic glomerulonephritis In pyelonephritis the polyuria can be severe enough to lead to the erroneous diagnosis of diabetes insipidus

In applying the ability to concentrate the urine to the assessment of the extent of the renal lesion one must not forget that, owing to the irregularity of spread of pyelonephritis, the specific gravity of the urine is that of a mixture of urine from damaged or destroyed nephrons with urine from relatively intact tubules Thus, a specific gravity of 1 020 can be the result of either moderately severe pyelonephritis of both kidneys or of a mixture of highly concentrated urine from one healthy kidney and of isosthenuric urine from the other kidney, but, when the specific gravity indicates isosthenuria, it means that there is widespread damage of both kidneys

A urinary specific gravity below that of plasma ultrafiltrate shows that, even with the most severe damage to their cells, the tubules can still absorb some electrolytes from the urine This is further shown by the result of the dilution test (fig 10) Though the ability to concentrate the urine is impaired in practically all cases of pyelonephritis (in some to a very considerable extent), the ability to dilute the urine to a specific gravity of at least 1 002 remains, with few exceptions, up to the last stages of the disease Like the concentration of the urine, the dilution of it is connected with the formation of an osmotic gradient between the blood and the urine in the tubules Fig 10 suggests that dilution and concentration cannot be viewed simply as two aspects of one and the same process, and that, of the two functions, concentration is much more vulnerable than dilution The reason for this difference is unknown

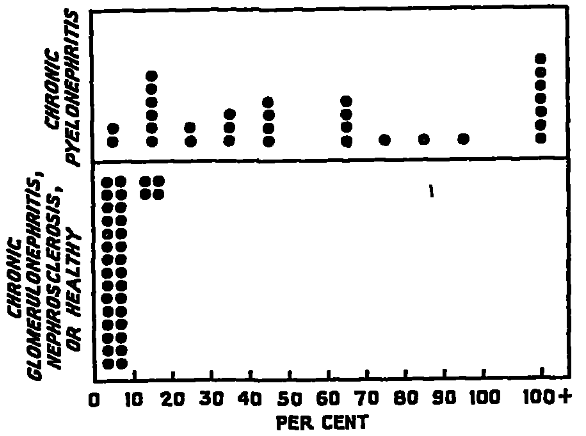

Fig 15—Individual differences in concentrating powers of right and left kidneys

The rôle of the distal tubules in regulating the acid base balance has so far been but little studied in disease and not at all in chronic pyelonephritis, where an alteration of this function may be expected V Fencl (unpublished work) therefore investigated in our laboratory the ability of our pyelonephritics to save base after the administration of ammonium chloride 5 g daily for two days In his preliminary studies he examined the twelve hour urine of the second night for ammonium and titratable acidity—i e, sodium ions exchanged in the distal tubules and used to replenish the alkaline reserve

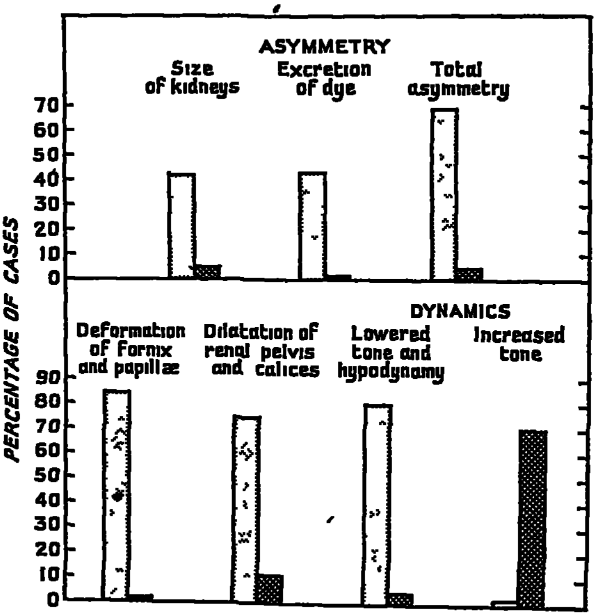

Fig 16—Radiological findings in 96 cases of chronic pyelonephritis (stippled) and 53 of chronic glomerulonephritis (cross hatched)

to suffer criminal or induced abortion, or sometimes *to have had their tubes tied inopportunely*

The incidence of extra-uterine gestation after such surgery has never been as high as 2% in London

London, W 1 V B GREEN-ARMYTAGE

TREATMENT OF TETANUS

SIR,—In our article in your issue of April 28 we produced evidence tending to show that the protracted administration of 50% nitrous oxide and 50% oxygen to patients with severe tetanus may lead to fatal aplastic anæmia Fairly conclusively it was shown that of the two components the acute bone-marrow depression was caused by the nitrous oxide and not by the oxygen

Major Sanders (June 2) calls our attention to the possibility that the pathological changes observed may have been caused by the prolonged use of oxygen at relatively high alveolar pressures This possibility has been in our minds, and we have consulted the available literature without encountering reports of acute bone marrow depression with fatal agranulocytosis following protracted breathing of oxygen at high partial pressures

Furthermore, as stated in our article, when in the two trials nitrous oxide was discontinued nothing else was changed in the treatment, including oxygen administration In other words, in these two patients hæmatological remission took place in spite of the continued use of 50% oxygen—nitrous oxide being replaced by nitrogen

Finally only this during the epidemic of poliomyelitis in Copenhagen in 1952 50% oxygen and 50% nitrogen was administered to more than two hundred patients treated with intratracheal positive pressure breathing This in many cases was kept up for several months without ever leading to the appearance of aplastic anæmia or agranulocytosis

Copenhagen

H C A LASSEN
ERIK HENRIKSEN

PLASMA FIBRINOLYTIC ACTIVITY IN CIRRHOSIS OF THE LIVER

SIR,—We have read with interest Dr Fearnley's letter of April 14, referring to our paper with the above title[1]

When our observations were made we were aware of Dr Fearnley's important contributions[2–5] to the study of fibrinolytic activity Regrettably our facilities were not such as to permit the employment of the low-temperature technique which he has described Being fully aware of the lability of the fibrinolysin, we were at pains throughout to ensure that all specimens of plasma under test were clotted by the addition of thrombin at a fixed time, 15 minutes, after obtaining the blood Observations on a series of normal subjects and on patients with cirrhosis of the liver had established that there was *no significant difference in fibrinolytic activity* between specimens of the same plasma kept at room temperature for 10 and for 20 minutes before the addition of thrombin Throughout our communication the expression "healthy controls" was used, and the findings in these controls only represented the fibrinolytic activity encountered in healthy subjects under the same conditions as the experimental observations They were not intended to represent the activity which might be encountered in *normal* subjects under other conditions

We are very much aware that serum is possessed of antifibrinolytic activity This activity, however, is vastly different from the inhibition of plasmin by the serum plasma inhibitor of plasmin In mixtures of plasmin and normal plasma a relatively slight reduction in the ratio of plasmin to plasma converts a clot which lyses in less than 30 minutes to one which *will not lyse at all*[6] These results can be reproduced using plasmin, a solution of fibrinogen and serum Normal plasma does not appear to be possessed of antifibrinolytic activity[6] On the other hand, we have found that normal serum significantly reduces fibrinolytic activity, but our observations indicate that this is a function of the concentration of the serum and the duration of incubation of the fibrinolytic plasma serum mixture before the addition of thrombin In contrast to the plasma of healthy subjects, that of patients with carcinoma of the liver has substantial antifibrinolytic activity, and this effect is enhanced by incubation The serum from such patients possesses greater antifibrinolytic activity than normal serum, but this is not increased by incubation Of perhaps greater interest is the markedly variable antifibrinolytic activity of the plasma of blood obtained from normal spleens at operation Typical examples of our results, showing the lysis time in hours, are set out in the accompanying table

Plasma or serum tested for antifibrinolytic activity		Duration of incubation before addition of thrombin	Ratio of fibrinolytic plasma to plasma or serum under test					
			1/0	1/1	2/1	5/1	10/1	[illegible]
Healthy control peripheral blood	Plasma	Nil 2 hr	4 5	6½ 8	6½ 6	6 5	6 [illegible]	5½ 5
	Serum	Nil 1 hr 2 hr	4 4½ 5	7½ 15 21	6½ 10 14	5½ 5½ 6	5 5 5½	4 5 5
Carcinoma of liver peripheral blood	Plasma	Nil 1 hr 2 hr	4 4½ 5	26 2/3 lysed 26 No lysis 26	13½ 18 19½	6½ 9½ 9½	6½ 6 6	5½ 5½ 6
	Serum	Nil 2hr	4 5	26 25½	17½ 18	7½ 8½	6 7	5½ 6
Blood from 2 normal spleens	1 Plasma	Nil	3	No lysis in 24 hours				
	2 Plasma	Nil	3	12	12	8	6	6

The fibrinolytic plasma was obtained from 2 patients with cirrhosis of the liver, and the amount employed in each test was constant The final dilution of plasma or mixtures of plasmas in veronal acetate buffered saline was 1/25

Invariably in our cases of cirrhosis of the liver we have found a complete absence of fibrinolytic activity in the plasma of blood obtained from the spleen removed at operation, yet during operation, both before and after removal of the spleen, there was intense fibrinolytic activity in the peripheral blood—in some cases so intense as to lyse in 4 minutes the clot formed by the addition of thrombin to whole citrated plasma The antifibrinolytic activity of the plasma of the splenic blood appears to vary even more widely than that of normal splenic blood

Since writing the paper referred to by Dr Fearnley we have followed up for longer periods the patients who were splenectomised and have extended our observations to many others We have found that increased fibrinolytic activity does not always reappear after the initial phase of inhibition following operation When it does so, as in the three cases reported, it subsequently disappears and *in all patients* increased fibrinolytic activity is no longer present 2 months after splenectomy It has remained absent in the follow up ranging up to 14 months, but observations on patients who have been splenectomised for more than 2 years suggest that increased activity may return, though with reduced intensity

The application of the observation that corticotrophin inhibits spontaneous fibrinolytic activity in cirrhosis of the liver to the prevention or control of bleeding associated with intense fibrinolytic activity had occurred to us While we have found that corticotrophin cortisone,

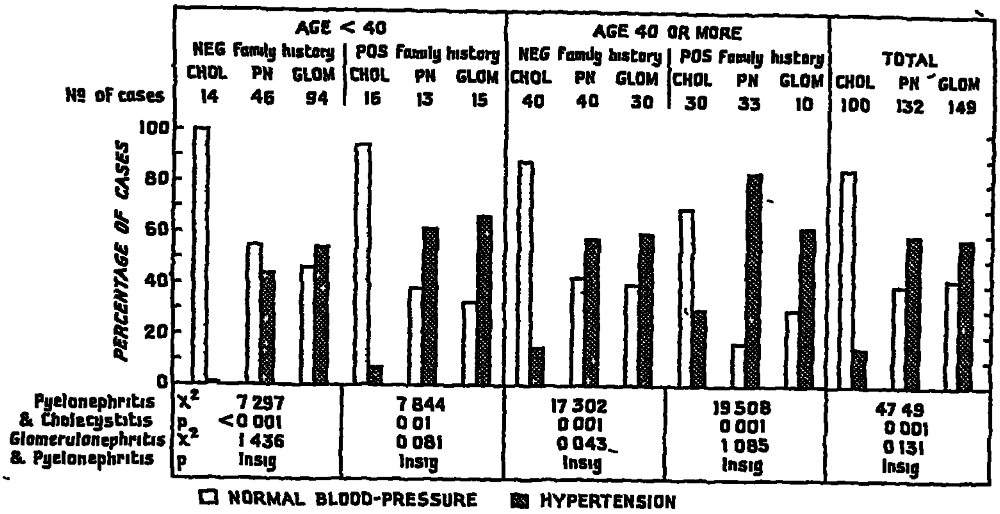

Fig 17—Incidence of hypertension in chronic pyelonephritis, chronic glomerulonephritis, and cholecystitis

A healthy man excretes in twelve hours 90 m eq of hydrogen and ammonium (fig 11) The same quantity of fixed base is saved to the body 11 5% of this saved base is accounted for by titratable acidity, and 88 5% by ammonia In chronic pyelonephritis with a mild reduction of function of the distal tubules (urinary specific gravity above 1 020) a slight restriction of this process may occasionally be found, but in patients with a urinary specific gravity less than 1 020 the efficiency of the whole exchange mechanism drops to about half, primarily owing to deficient production of ammonia This follows from the fact that the proportion of saved base accounted for by titratable acidity increases to 17 4% The hydrogen exchange is, however, limited by the concentration of hydrogen ions in the urine excreted by the tubules Hence a consequence of this reduction of the ability to excrete ammonia is the loss of fixed base which accompanies radicals of stronger acids in the urine This permanent loss of sodium from the body tends to produce dehydration, especially if a salt free diet is inadvertently prescribed for the patient

The failure of the tubules to excrete hydrogen into the urine may increase the hydrogen ion concentration within the cells of the tubules This would initiate a vicious circle by still further depressing the production of ammonia from glutamine, the optimal pH of glutaminase being 7 8 The intracellular acidosis probably causes increased loss of potassium from cells of the tubules Although potassium enters into the base saving mechanism in the urine in the tubules, being exchanged partly for sodium bound by stronger anions, its losses further complicate the disturbance of the electrolyte metabolism in advanced pyelonephritis On the other hand, this increased loss explains why we have never found potassium accumulating in the extracellular fluid, even in the most advanced stages of pyelonephritis with an extremely low glomerular filtration rate, in spite of the fact that under these conditions the accelerated breakdown of tissue proteins releases much potassium into the extracellular fluid

The restriction of sodium exchange in the distal tubules and the permanent loss of fixed base from the body decrease the alkaline reserve and produce acidosis There is a very good correlation between the decrease of concentrating power and that of the alkaline reserve to low values Fig 12 shows that only 4 patients with a urinary specific gravity above 1 020 had an alkaline reserve below our lower normal limit (53 vol %), and only 4 patients with a urinary specific gravity below 1 020 had a normal alkaline reserve The correlation with glomerular filtration-rate is slightly less satisfactory (P=0 496) However, all the patients in whom this function was severely reduced were acidotic No doubt, in these patients ther was a very severe lesio of the tubules and katabolism exceeded anabolism

Calcium and Phosphoru Metabolism

Chronic acidosis i usually connected wit disturbances of calcium and phosphorus metabolism a fall in the plasma phosphate level, whereas the plasma calcium level is normal o slightly below normal, provided the glomerula filtration rate is normal Fig 13 shows that th was not what happened in our pyelonephritics We found changes in the ratio of plasma calcium and plasma phosphorus levels in only the most advanced cases with a urinary specific gravity below 1 013 These changes, however, consisted in a rise in the plasma phosphate level and a fall in the plasma calcium level

Simple parathyroid hyperfunction as a consequence of increased urinary excretion of calcium in these acidotic patients was clearly an inadequate explanation Analysis revealed that the rise in the plasma phosphate level was the primary event This was obviously a consequence of the much reduced filtered load of phosphate, even the greatest possible increase of parathyroid secretion in these patients who were chronically losing calcium in their urine and a great reduction of the power of the tubules to reabsorb phosphate were insufficient to restore their plasma phosphate level to normal Probably the plasma calcium level dropped partly as a consequence of its increased urinary excretion in acidosis This excretion, however, was not significant enough to produce detectable osteoporosis Although the amount of alkaline phosphatase was slightly increased in the patients in this last group, no significant demineralisation of the bone, or cyst formation, was found on radiography in any of our patients with a far advanced renal lesion Biopsy specimens of bone obtained in some of our patients during lumbotomy did not reveal any changes in the structure of bone

Ureteric Catheterisation

I have been dealing so far with the effect of interstitial renal inflammation on the function of the neighbouring

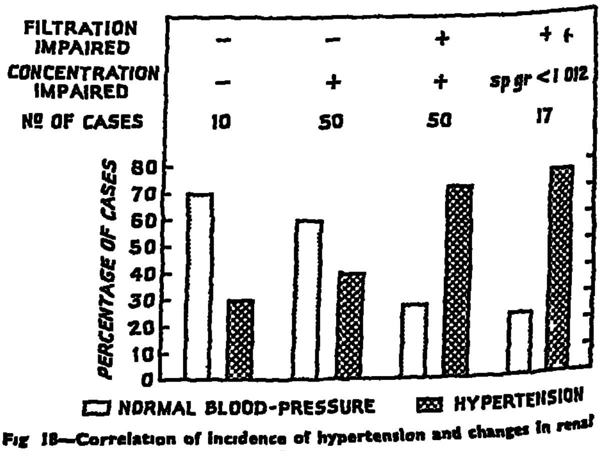

Fig 18—Correlation of incidence of hypertension and changes in renal function

control have ceased to be employed. It appeared to me that then only could the proper study of insanity begin, the removal of restraints, and of all violent and irritating methods of control, then first permitting the student to contemplate disorders of the mind in their simplicity, and no longer modified by exasperating treatment. Patients could then be presented to their observation as subjects of study and reflection." [7]

Psychiatrists were for the first time enabled to study and investigate in detail the minds of their patients. This in turn led in 1853 to the issue of the first number of *The Asylum Journal of Mental Science* published "by the Authority of the Association of Medical Officers of Asylums and Hospitals for the Insane" ‡. The further development of psychiatry in the second half of the nineteenth century bears ample evidence of the fruits of Conolly's labours.

THE RETURN OF RESTRAINT

A despondent, perhaps prophetic, state of mind to which Conolly was at times subject led him to fear lest the selfish interests of mankind might lead to reaction, and that much of his work might after all be lost to the world. "It seems to have been in some such mood that at the conclusion of his last work he was led to express an anxious hope, that nothing should be allowed to interfere with its continuation, that no future economy and no delusive theories would ever lead to the abandonment of '*non-restraint*' *in the treatment of the insane*." [10] §

In insanity the dividing line between treatment and restraint is very fine, and Conolly's forebodings were justified. "Chemical restraint of the cells of the sick brain" took the place of the old "mechanical restraint of the body." [11] Thus bromides (1857), chloral (1869), paraldehyde (1882), and barbiturates (1903) were all in turn considered harmless non-addicting specifics for mental disorders, and each allowed restraint disguised as treatment to slip back unobtrusively into the care of the insane. Some recognised the danger.

> "The successful argument against mechanical restraint was, that although it kept the patient's body quiet, it really *aggravated his malady*. *the question now which should be* considered is, whether chemical restraint does permanent good, or whether by diminishing excitement at the ultimate cost of mental power it 'makes a solitude and calls it peace.'" [11]

Since the 1930s psychiatry, jealous perhaps of the therapeutic advances in general medicine, has seen a spectacular rise and spread of "physical methods of treatment." In various forms such methods have always enjoyed a vogue ‖. Like the drugs which in part they replaced, they also were not abandoned in mental-hospital practice when they failed as therapies. Like drugs they remained as instruments of restraint in the guise of treatment. hypoglycæmic, electrical, and neurosurgical. The frequently made statement that electrical or chemical restraint is essential for keeping the peace in chronic or refractory wards of mental hospitals is shown by the experience of Cameron et al [8] to be fallacious. They demonstrated once again that better results can be achieved by skilled mental nursing. New drugs continue to be synthesised and with them claims that during their administration disturbed patients require less physical treatments. At the same time reports are published demonstrating reduction in drug bills made possible by more regular use of E C T. "since the introduction of electrical *treatment, the modern trend has* become more to rely on this in intractable cases." [13]

A KEY POSITION LOST

What does this development mean to the status of the mental nurse, deprived of the very functions to which mental nursing owes its inception—that is, to counter alienation by sustained, kindly human understanding and contact. When patients are controlled or suppressed by drugs or electricity all respect for them as mentally sick persons is lost. "when the patient is tied up, all regard for him ceases." [7]

The latest edition of the Royal Medico-Psychological Association's Handbook for Mental Nurses [13] speaks openly of restraint. It has almost nothing to say on the nurse patient relationship, which does not appear in the index of the book. To restraint there are three references.

> "*If a patient shows continued or oft repeated violence*, special measures may be necessary. The doctor may consider sedation advisable. This form of treatment is sometimes known as *chemical restraint*."
>
> "Under certain conditions the doctor may occasionally decide in favour of *mechanical restraint*."
>
> "'Sedation' can be effected in three main ways, by *drugs*, by *hydrotherapy*, and by *electrical treatment*. it brings the psychiatric patient to a more controlled level of behaviour."

In various parts of the book E C T is recommended as effective in the neuroses, psychoses, and organic states. Can a procedure which covers pretty well all aspects and degrees of mental illness be treatment, or is it restraint? Added to this, two new classes of auxiliaries curtail the nurse's direct responsibility for, contact with, and knowledge of the patient—social workers and occupational therapists. Under such a régime the mental nurse at worst spends her time polishing floors, at best she is allowed *to participate in the administration of physical* treatments. Her functions are reduced to less than those of a general nurse, and her status and conditions of work are often lower.

The shortage of nurses as well as of doctors for the staffing of mental hospitals is sometimes brought forward as the excuse for widespread physical treatments, ¶

> " until, by slow but very sure steps, restraints become the usual substitutes for attention, for patience, for forbearance, and proper superintendence. The tendency to neglect those who are deprived of reason still exists, and demands vigilant opposition. What the old system of treatment by restraint really was ought, therefore, not to be forgotten. Its evils were not imaginary, but real and dreadful. they must remain common, however disguised, wherever the system of restraint remains the subject of eulogy." [7]

Especially in a textbook designed for mental nurses.

Physical treatment replacing shortage of nurses starts a vicious circle of fewer nurses, more restraint disguised as physical treatment, less nursing, fewer nurses, more restraint, and so on. Dr Cameron and his colleagues have shown how much can be done with the minimum of well-guided staff. Who will have the courage to repeat the experiment on a large scale so successfully concluded by Dr Conolly in similar circumstances one hundred years ago? He will not find himself short of mental nurses when they are reinstated to their key position.

---

‡ It is now called the *Journal of Mental Science*, and the association has become the Royal Medico Psychological Association.

§ The element of restraint is hardly disguised when results of physical treatments are given in terms of "social recovery" or "more controlled behaviour," which significantly appear often in reports of the most permanent form of brain destructive restraint—leucotomy.

‖ As Fulton [12] pointed out, even the use of electricity (in the shape of the electric eel or torpedo) is "a fine old Roman custom introduced in the first century A D by Scribonius Largus." Of course, the operation of trepanning with variable damage to the underlying brain is the oldest procedure known to medical history.

¶ "Dr Conolly was praised for the abolition of restraint but it was not this which ought to be admired so much as his pluck and determination in doing away with it at short and definite notice in a county asylum with a relatively small staff, where many patients had been made intractable by the abuse of restraint." In England Now

A Running Commentary by Peripatetic Correspondents

AT 2.10 A.M. the other night I was wakened with the news that the girl in the room below had been badly burnt. She was warming herself in front of the gas-fire, when her cotton nightdress caught fire. I phoned the local hospital which I know specialises in burns, and has a large ambulance depot, and asked for an ambulance. I was told politely that I must dial 999. I rang 999, gave the address, and again asked for an ambulance. The operator, having taken down the name and age of the patient and my own name (though not age), announced that an ambulance would come immediately.

The owner of the house and I were administering hot sweet tea and packing a suitcase for the patient when there was a loud bang on the front-door. Four firemen were standing on the door-step, and, parked in the road was an immense fire-engine complete with a giant ladder. They inquired where the baby was. I explained there was no baby, and no fire, but eventually it transpired that the fire service turns out for every emergency call involving burns, whether or not there is a fire to be put out. The house shook as four pairs of heavy boots lumbered upstairs. The officer in charge made a note of the name and age of the patient, the name of the landlord, and the age of the house. He pointed out there was no fire-guard on the gas-fire. Finally he turned his attention to the girl on the bed, shivering from shock and cold. One of the men stamped downstairs, to return a minute later with a small cardboard box containing a sterile sheet. Then a police inspector suddenly appeared in the room, presumably let into the house by the fetcher of the sterile sheet. While I draped the sheet round the patient's burnt limbs, the police officer asked the now customary set of questions. He also commented on the absence of a fire-guard.

The room seemed a trifle crowded with five men and two women standing round the bed, but it became even more so a few moments later when three ambulance-men joined the party. Their senior officer once again asked the name and age of the patient, the name of the landlord, and the age of the house, and he, too, looked accusingly at the gas-fire and muttered something about no fire-guard. After these formalities, the patient was taken downstairs, accompanied by eight men, one stretcher, and a night-bag. Neatly parked outside the house were the fire-engine, the police-car, and the ambulance. It was then 3 A.M.

We were on the point of creeping back to bed when there was another hammering on the door. Three shame-faced firemen and one policeman stood in a row. The policeman wanted to know if we had the address of the patient's parents; the firemen had left something upstairs and went up to fetch it. It was the little cardboard box which had housed the sheet.

* * *

We flew from Accra to Freetown on a Sunday, stopping first at Abidjan (Côte d'Ivoire). The local French had turned out in force to meet a plane from Paris. In the restaurant the men, in very short shorts, sipped *apéritifs* and greeted all and sundry with perfunctory handclasps, while the women, wearing tropical clothes with all the *chic* of the Rue du Faubourg St.-Honoré, chatted vivaciously. We *transitaires* enjoyed an excellent hors-d'œuvre, followed by a *ragoût* and a bottle of Beaujolais. The only solecism was the *toilette* which was distinctly superior to metropolitan standards.

Our next stop was Robertsfield. Liberia is not an American colony (though cynics sometimes call it a colony of the Firestone Tyre Company), but it has a historic link with the States, and Robertsfield is run (with superb efficiency) by Pan-American. Well, if the French have gallicised their colonies, Pan-Am have certainly americanised Robertsfield. An air-conditioned passenger lounge, a large portrait of President Eisenhower with a warm-hearted message to travellers below it, and coffee or 'Coca-Cola' for those in need of refreshment. The final touch is provided by African airport police, in American uniform, each with a revolver on his hip and a sloping bandolier of cartridges.

* * *

As it was my third visit to the outpatient department, I knew the procedure and could watch with haughty disdain the new patient who sat and moved along with the old patients. I was surprised that she was not severely reprimanded, as I had been when I did the same on my first visit. But perhaps she was let off because the young clerk was not there to marshal us on this occasion. This was lucky, for I was able to collect my notes in front of those who were waiting patiently for authority to direct them. I took my place in the line of waiting patients and in an attempt to estimate the delay before seeing the specialist I asked my neighbour, a solid late middle aged woman, if she had been here long. I was appalled at her reply "Three years," but reassured when after a pause she added "off and on," and then dismayed again when, entirely disregarding Hippocrates and all that, she expounded her views of her husband's illnesses.

It transpired that it was he who was ill, but if she didn't come with him, he would sit in the hospital all day and let everyone go in front of him. He suffered from his nerves, an ulcer, and glaucoma. *The acidity from the stomach accumulates in his body and burns his nerves which make the eye contract so that it almost blows up at times.* The hospital had given her some wonder drops which you could only get from the hospital. They were called Tid and had to be given three times a day; she had tried to get some from the chemist for a friend, but the chemist had never heard of them. Amazing how these ignorant people were allowed to practise in the health service at all. Where would we be without the hospital doctors?

Take her own case, she developed a giddiness of her eyes *(if I got her) about 18 months ago, or was it 19?* Anyway she went to her own doctor and he said it was her nerves; then she insisted on seeing an eye specialist at the hospital and he said there was nothing the matter with her eyes. Just fancy, if she hadn't seen the specialist she might still be having treatment for her nerves. Not that she really believes in all this nerve business. Take her own husband, she always tells him it's only will power. If he really put his mind to it he needn't have any of this ulcer or glaucoma business.

At this moment Sister appeared and said, "Doctor Blank, would you come in now please." As I left my loquacious companion I heard her turn to her next neighbour and remark:

"Fancy him being a doctor. I wouldn't have told him all my ills if I'd known. Doctors aren't allowed to discuss illness you know, the Minister of Health might strike them off if he caught them. That's why some have secretaries, so they can tell the patients what's the matter with them."

* * *

Newspapers treat the hospitals more and more as though they had ceased to be institutions; but why, oh why, when someone goes to hospital, are there still only *two* alternatives open to him? He is either "detained" or "allowed to go home." Even the Liberal dailies suffer from this aberration.

* * *

In our sanatorium we sent a lot of patients home on leave for Christmas; in fact, in one ward, only six Pakistanis and an East African were left. But the carol-singing nurses who visited the ward at midnight on Christmas Eve firmly started their programme with "Christians Awake!"

* * *

At today's domiciliary visit the consultant wanted an electrocardiogram. To everybody's surprise the electrocardiograph produced sweet melodies from the nearby television station instead of T waves and Q waves.

G.P. (jokingly): "You'd better ring them and tell them to stop their show."

Cardiologist (seriously): "I certainly will." And he did.

The reply was: "In one and a half minutes we will stop for two minutes." And they did. The E.C.G. was taken without any interference.

Cardiologist: "You'd better ring them again and tell them that we are grateful for their coöperation."

G.P. on the phone: "Thank you very much for stopping; we managed fine in those two minutes."

B.B.C. Engineer: "Good show."

nephrons I have already emphasised that chronic pyelonephritis spreads irregularly, and that there are usually great differences in its extent in the two kidneys I therefore tried to assess the function of the two kidneys separately After much futile effort, we decided to make do with a study of separate concentrating indices of endogenous creatinine ($\frac{U}{P}$ ratios) in the urine obtained from the two kidneys by ureteric catheterisation The results of this study, made by my collaborator Prat (1955), are shown in fig 14, where the differences in the $\frac{U}{P}$ ratios of the two kidneys are expressed as percentages of whichever ratio was the lower This difference was insignificant in 13 healthy people (6 0%), in 13 patients with chronic glomerulonephritis (3 6%), and in 7 with vascular nephrosclerosis (5 9%), whereas in 31 patients with chronic pyelonephritis the average difference was 78 3% for the whole group, being 123 6% in those in whom there were other reasons to suspect unilateral disease, and 53 5% in those in whom no difference between the two kidneys was indicated on other grounds The diagnostic importance of this finding is clear, especially since the data for the individual cases (fig 15) show very little overlapping

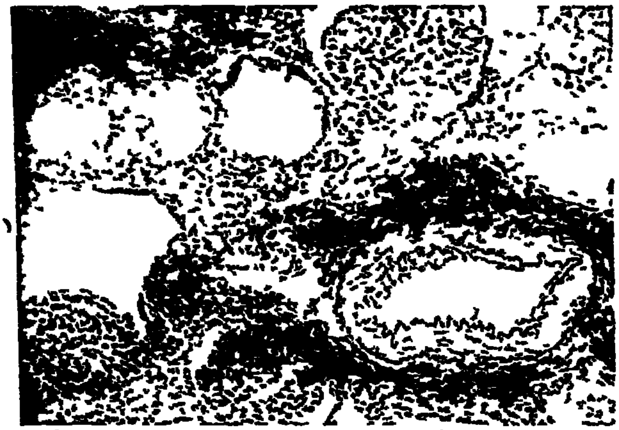

Fig 19—Section of biopsy specimen of contracted kidney in unilateral chronic pyelonephritis with malignant hypertension cured by nephrectomy

Radiography

There has been much controversy about the usefulness of radiography in establishing the diagnosis of chronic pyelonephritis Radiography is, of course, necessary to show anatomical abnormalities of the urinary tract, but it has been doubted whether it can afford further information about the state of the kidneys

Improved methods of diagnosing pyelonephritis enabled my colleague Dejdar (1955) to reinvestigate this question The result was rather surprising of 96 patients in whom chronic pyelonephritis was diagnosed on clinical grounds it was possible to demonstrate in 70% an asymmetry between the two kidneys This was shown by the size and density of the renal shadow and by the speed at which the dye appeared in the renal pelves (fig 16) In the control group of 21 glomerulonephritics such an asymmetry was found in only 4% Further, when serial radiographs were taken in the first few minutes after the injection of dye to gain some idea of the function of calices, pelvis, and ureter, and attention was paid to residues of the dye in the pelvis and calices fifteen to thirty minutes later, a failure of proper contraction and evacuation of the dye—either hypotony or atony—was discovered in 80% A hypotonic urinary tract was found not only in patients with a primary lesion in the urinary tract but also in patients with primary pyelonephritis This discovery supports the view expressed above that a functional disturbance of the urinary tract without any anatomical obstruction may facilitate infection and its further spread to the kidneys This was in sharp contrast to the findings in glomerulonephritics, such changes being found in only 3 7% of such patients, and being neither severe nor widespread On the other hand, spastic calices were found in 69 9% of the glomerulonephritics but in only 1% of the pyelonephritics in whom they were unilateral, whereas in glomerulonephritics they were bilateral

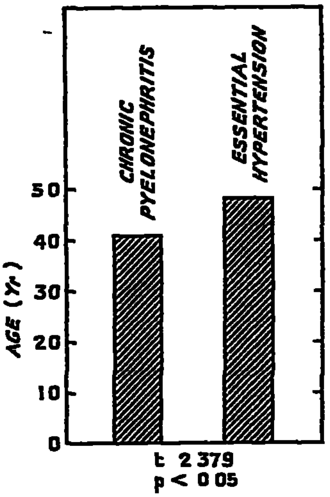

Fig 20—Average ages of patients with malignant hypertension

Hypertension

Our progress in the clinical diagnosis of chronic pyelonephritis shed more light on hypertension in chronic pyelonephritis Investigators in this field are divided into several groups most of them seem to accept that hypertension is present, at least in the late stages, but opponents of this view—e g, Bell (1950)—do not acknowledge any link between pyelonephritis and hypertension Goldring and Chasis (1944), who deny such a connection, at least in unilateral pyelonephritis maintain that hypertension is then coincidental Schroeder and Steele (1941) hold the extreme view that chronic pyelonephritis underlies most cases of essential hypertension, their conclusion being based on minor abnormalities in the pyelograms

We therefore compared the prevalence of hypertension (blood-pressure over 145/95 mm Hg, special attention being paid to the diastolic pressure) in our 132 pyelonephritics and in 100 patients with chronic cholecystitis selected at random (fig 17) The controls were selected from patients because of our previous finding that any organic disease might disturb the vasomotor mechanisms (Brod et al 1954) We also studied hypertension in glomerulonephritis

The average age of our patients with cholecystitis was somewhat higher than that of those with pyelonephritis,

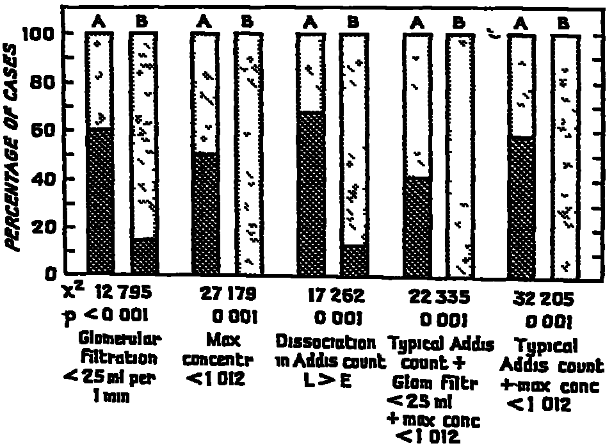

Fig 21—Renal function in malignant hypertension due to chronic pyelonephritis (A) and in essential hypertension (B)

(2) Postoperative bleeding necessitating reopening of the wound, evacuation of clot, and suture of a bleeding point on the right side—the right nerve was damaged.

(3) A large retrosternal gland on the left side, but the right nerve was damaged.

(4) A second operation with a retrosternal prolongation on the right side, and the right nerve was injured.

No Recovery of Movement of Cord

Of the 22 cases (7·3%), including 2 bilateral cases, in which no movement of the cord was recovered, 14 showed excellent compensation by the opposite cord. This occurred soon after operation and compensation was complete in 10 cases. So good was the compensation in these 10 cases that when they were examined recently for this review, it was not suspected until the larynx was examined that the cord had not recovered. These patients could sing and shout and described their voices as perfect. 4 of them had not noticed any abnormality in their voices even shortly after operation. The other 4 had compensated fairly well but still had some huskiness or found that their voices were easily fatigued, being normal for only the first few minutes of speech. Nevertheless all had shown considerable improvement and did not consider that they were handicapped by this weakness.

This left 8 cases (2·7%) with no improvement and included the 2 cases with bilateral paralysis where compensation was obviously impossible. All these patients had voices which were husky and easily tired, and in the bilateral cases the voices had a “ brassy quality ” with some inspiratory stridor.

In 15 of these cases difficulties were noted during the operation, whereas in the other cases the operation appears to have been uneventful. The difficulties were as follows:

(1) A second operation for removal of a diseased right lobe with a retrosternal prolongation. The inferior thyroid artery could not be seen on the right side and was not tied. There was considerable bleeding during the operation, and two days later the wound was reopened for evacuation of clot and control of bleeding. The right nerve was damaged.

(2) A large retrosternal prolongation on the left side. The left nerve was damaged.

(3) A very vascular gland which bled postoperatively and necessitated reopening of the wound on two occasions for evacuation of clot and control of bleeding.

(4) A second operation with a difficult dissection, and the nerve was seen to be divided at operation.

(5) A large friable gland with a retrosternal prolongation on the left. The left nerve was damaged.

(6) A large gland with retrosternal prolongations on both sides, and the left inferior thyroid artery was not tied. The left nerve was damaged.

(7) A large retrosternal prolongation on the right side. The right nerve was damaged.

(8) A second operation with a retrosternal prolongation on the left side. The left nerve was damaged.

(9) A retrosternal prolongation on the right side. The right nerve was damaged.

(10) A second operation with a difficult dissection on the right side. The right nerve was damaged.

(11) A second operation, and the left inferior thyroid artery was not tied. There was considerable bleeding, and the left nerve was damaged.

(12) A retrosternal prolongation on the right side and the inferior thyroid artery on the right side was not tied. The right nerve was damaged.

(13) A very large nodular right lobe. The right nerve was damaged.

(14) A very large hæmorrhagic gland. Both nerves were damaged.

(15) A second operation with a retro œsophageal prolongation on the left side. The left nerve was damaged, and the right nerve had been damaged at the first operation in 1925.

There was no record in any case of any abnormality in the anatomy of the neck except in so far as it was produced by the diseased gland.

The following is a summary of the difficulties met with in 19 cases:

11 cases with retrosternal prolongation of a lateral lobe.

7 cases where a second operation was being done.

5 cases in which hæmorrhage was severe, and in 3 cases the wound had to be reopened.

1 case where there was a retro œsophageal extension of a lateral lobe.

There were 21 cases in which no difficulty was noted at operation. In these cases the proportion of right nerves injured to left nerves injured is 2 : 1 (14 : 7 cases). This is higher than the proportion for the whole series (23 : 18) and seems to be significant.

Discussion

The first important fact emerging from this review is the frequency of 13·3%, which was far higher than expected. This shows a close correlation with Wade’s (1955) conclusion that 15% of recurrent nerves are in absolute or partial danger during thyroidectomy. This fact is revealed because each case was examined irrespective of whether the patient complained of a voice change or not. If we had examined only those who complained of voice changes at a follow-up attendance, the frequency would have been 4–5%.

It was to be expected that a damaged recurrent nerve could recover. It is presumed that, in cases showing early recovery, the nerve lesion was due to stretching, causing neurapraxia, whereas in the few cases that took over six months to recover the axons had been damaged (axonotmesis) without disruption of the sheaths, possibly by being crushed in a hæmostat. This is suggested by the 4 cases that showed full movements of the cords but still had some slight impairment of voice function. In the 1 case where the nerve lesion initially appeared to be partial and later was certainly complete we suggest that fibrosis following hæmorrhage round the nerve had produced this effect; but it is only an isolated case and perhaps the occasional difficulty in examining the larynx soon after operation may, in this case, have led us to classify as partial a lesion which was, in fact, complete.

Although it is well known that where the nerve does not recover, compensation can be good, we were surprised to find it so good in so many cases. In the 10 cases that showed complete functional recovery great care was taken to ascertain that this was really so. Only 6 unilateral cases (2%) showed no significant recovery.

As regards the causes of damage to the nerves, in 19 cases where difficulties were noted by far the most common difficulty was that presented by a large retrosternal prolongation of the gland (11 cases). This suggests that the nerves are more vulnerable the lower the dissection proceeds. At this level a greater proportion of nerves are in an exposed position lateral to the tracheo œsophageal groove, and when the lobe is delivered the nerve is drawn forwards with it. Certainly it seems that special care is required in delivery of a retrosternal prolongation of the gland; though a blind dissection may be necessary it cannot be assumed that the nerve is out of danger.

Many workers have drawn attention to the vulnerability of the nerves when they lie in a variable relationship to the inferior thyroid artery, but the nerves are also in danger at a lower level. When a retrosternal prolongation or a lower-lobe adenoma is dislocated upwards and forwards, the nerve is also drawn forwards. Though it is debatable whether the nerve should be dissected through-but it is clear that hypertension was four times as common among our pyelonephritics as in the controls 59 7% compared with 15 0%

In patients aged more than 40 and with a family background of hypertension the prevalence was 84 85% in pyelonephritis and only 30% in cholecystitis Here we cannot deny a possible coincidence with essential hypertension, 85% being almost the sum of the prevalence of hypertension in older pyelonephritics with a negative family history and the 30% prevalence in patients with cholecystitis with a positive family background However, even in young patients with a negative family history hypertension was present in 43 5%, whereas it was not found in any control patient of the corresponding subgroup The difference between pyelonephritis and cholecystitis is statistically highly significant

On the other hand, there is no difference between the prevalence of hypertension in pyelonephritis and glomerulonephritis in any of the subgroups, and the over-all prevalences of hypertension in pyelonephritis and in glomerulonephritis are almost equal, that in glomerulonephritis being 58 1%, indicating that the blood-pressure is raised by the same mechanism in both diseases

Hypertension develops with increasing frequency as pyelonephritis progresses, but hypertension was found in 14 (43 8%) of 32 patients with a normal glomerular filtration-rate and in more than 20% of patients in whom all renal functions were only a little damaged (fig 18) Thus there can be no reasonable doubt about the causal relationship between chronic pyelonephritis and hypertension, which can be brought about even by slight disease

As regards the mechanism by which hypertension develops one can but speculate, but our biopsy studies (Brod and Benešová 1955) refute the theory of Weiss and Parker (1939) that arteritis induced in renal vessels by the surrounding inflammation may be the starting-point in 5 of our patients with grave hypertension such lesions were either absent (fig 19) or minimal, and in 3 patients with hypertension vascular changes were of the type found in experimental hypertension

A very important complication of pyelonephritic hypertension is malignant hypertension, diagnosed on changes in the retinæ Of 76 pyelonephritics with hypertension this complication developed in 15 (19 7%) This was significantly more than the 10% prevalence of malignant hypertension in our 490 patients with essential hypertension There was, however, no significant difference in the prevalence of severe diastolic hypertension (above 130 mm Hg) between chronic pyelonephritis and essential hypertension Malignant hypertension came on at an earlier average age (41 67 yr) in chronic pyelonephritis than in essential hypertension (48 59 yr) (fig 20), the difference being statistically significant

From the renal aspect an important difference was found between these two diseases as regards malignant hypertension whereas essential hypertension can become malignant at any level of glomerular filtration or concentrating ability, in chronic pyelonephritis hypertension tends to become malignant only with far advanced renal disease The difference is statistically significant ($P<0 05$) Whereas a reduction of the glomerular filtration rate below 25 ml a minute was found in 60% of patients with malignant hypertension in pyelonephritis, it was found in only 10% of patients with essential hypertension (fig 21) Inability to concentrate the urine to sp gr 1 012 was not found in malignant hypertension per se, but it was found in 50% of our pyelonephritics with malignant hypertension

The Addis count further differentiates patients with malignant hypertension due to pyelonephritis from those with malignant hypertension following essential hypertension the typical prevalence of leucocytes in the urinary deposit was found in almost 65% of the pyelonephritics but in only 10% of the patients with essential hypertension Therefore a combination of a glomerular filtration-rate below 25 ml a minute, inability to concentrate the urine to sp gr 1 012, and a majority of leucocytes in the Addis count are pathognomonic of malignant hypertension due to chronic pyelonephritis

A combination of a low urinary specific gravity and Addis count gives an equally sharp differentiation between the two diseases The diagnosis thus established was confirmed by either biopsy or necropsy in most of the later cases

Clinical Entity of Chronic Pyelonephritis

In most of the patients included in this study the clinical diagnosis of chronic pyelonephritis was based (apart from the history) on the dissociation between the disturbances of glomerular and tubular functions and the dissociation between leucocytes and erythrocytes in the Addis count New criteria were added only slowly as our experience of chronic pyelonephritis increased, and our present knowledge comes only from the analysis of the whole group Is it, therefore, possible that we have collected an artificial group which, although presenting this double dissociation, is really of heterogeneous pathology? I think that this question can be answered in the negative Not only was our diagnosis confirmed by the pathologist wherever possible, but also the alterations in almost all the functions which have been discussed separate our group of chronic pyelonephritis sharply from the other renal diseases and reveal a uniform behaviour within the group

Treatment

Little advance has been made in the treatment of chronic pyelonephritis Chemotherapy and antibiotics are insufficient The chief difficulty lies in the fact that a kidney which has once been damaged is a locus of predilection for any blood borne organisms, and that an abnormally functioning urinary tract predisposes to infection of the renal pelves We can do little towards functional restitution of the pelves once their elastic and muscular elements have been superseded by fibrous tissue

Our not very satisfactory therapeutic regimen can be summarised as follows

(1) Prevention of disturbance of the urinary tract and intensive treatment of such disturbance

(2) Prevention of infection and careful elimination of all focal infection in a patient in whom the function of the urinary tract is disturbed, and intensive treatment of every infection in the urinary tract

(3) Antibiotic therapy strengthened, if possible, by regulating the reaction of the urine

(4) Care of the bowels, with proper hygiene of the abdominal wall

(5) Sexual hygiene

(6) Saving of osmotic work of the diseased tubules by the dietetic principles of Addis

(7) Salt restriction never to be prescribed unless there is some special reason for it—e g, heart failure

(8) Possibly treatment in a sanatorium, to improve the patient's general condition and his resistance to infection

(9) Renal denervation or an attempt to remove sclerosed fat from the renal hilus in progressive cases

(10) Where unilateral disease leads to hypertension (especially the malignant sort), nephrectomy to be considered

With such purposeful treatment we have occasionally seen striking results In several cases malignant hypertension was made to recede, and in 1 case nephrectomy completely cured malignant hypertension, but such striking successes have hitherto been the exception rather than the rule Too many patients are still referred to us with irreversible changes of the urinary tract, terminal changes in the kidneys, or a seriously damaged cardiovascular system It is possible today to recognise chronic pyelonephritis even in its earliest stage by methods which out its course in the neck, it is certain that care should be taken that only the inferior thyroid veins are divided at the lower pole, and the web of tissue should be carefully teased out and scrutinised before hæmostats are applied or ligatures tied Dislocating a diseased lobe may cause an injury from which the nerve will recover, but it can easily be converted into a permanent injury

In 7 cases the gland was being explored for a second time, and it is obvious that there is then greater difficulty in exposing the gland and avoiding damage to the nerve It may be suggested that in these cases it would be wise to expose the nerves if possible, but we feel that the dissection necessary for exposure would itself cause damage In 3 cases severe postoperative bleeding necessitated reopening of the wound to control bleeding, and it is obvious that great care should be taken to avoid the nerve, but bleeding from an area near the nerve must be controlled, and the risk of nerve damage accepted

In 21 cases (7%) no operative difficulty was noted and yet one of the nerves was damaged In 14 of these cases the nerve recovered, presumably the nerve was either stretched or caught in a hæmostat in these cases It has already been pointed out that the right nerve was damaged twice as often as the left in these cases Bowden (1955) has recently concluded that, from anatomical considerations alone, there is an inherent risk of damage to the nerves during thyroidectomy She points out that the nerve takes an irregular course on the right side more commonly than on the left She also found that, at the level of the gland, only 73 of 134 nerves on the right, and 85 of 133 nerves on the left, were lying in the tracheo œsophageal sulcus, the rest were in an exposed position Again the right nerve seems to be slightly more vulnerable

Conclusions

We agree with Bowden (1955) that there is an inherent risk of damage to the recurrent laryngeal nerves during thyroidectomy, and we add that the risk is greatly increased in the presence of certain pathological conditions of the gland, of which the most important is the retrosternal *prolongation* of the lateral lobes

We emphasise the danger to the nerves at quite a low level in the neck in the presence of lower-lobe adenomata and retrosternal *prolongations*, in *addition* to their vulnerability where they are crossed by, or mingle with, the branches of the inferior thyroid artery It is in these cases that permanent damage to the nerves can be avoided

The prognosis of the damaged nerve is good Many recover In those that do not recover, compensation by the other cord is usually good and functional recovery rapid and often complete

Summary

In a series of 300 consecutive thyroidectomies 39 patients sustained damage to one recurrent laryngeal nerve and in 1 case both nerves were damaged

In 18 cases the damaged nerve recovered completely, while in 22 cases recovery did not occur The causes of damage to these nerves is discussed and their recovery of function assessed

An accurate estimate of the frequency or extent of damage to the recurrent laryngeal nerves can only be obtained if the vocal cords are examined both preoperatively and postoperatively, preferably by an ear, nose, and throat surgeon

Our thanks are due to Mr Robert Strang for permission to include his cases in this review

KING'S COLLEGE HOSPITAL, LONDON

THE word "steroid" is a "generic name for a group of compounds comprising the sterols, bile acids, heart poisons, saponins and sex hormones" (Grant 1949) Fifteen years ago Selye began an investigation into the anæsthetic properties of a large number of steroids (Selye 1941a and b, 1942a and b, 1943), all of which, except pregnanedione, exhibited hormonal activity Recently these results were reviewed by Laubach et al (1955), and the results of pharmacological experiments suggested that a derivative of pregnanedione (21 hydroxy pregnane 3, 20 dione, sodium hemisuccinate) ('Viadril') might be suitable for human anæsthesia The drug was sufficiently soluble in water to be given intravenously, it had a far higher therapeutic index than thiopentone, it was not carcinogenic, and it showed no signs of hormonal activity, such as salt retention This drug was released for simultaneous clinical trials in the U S A (Gordon et al 1955, Murphy et al 1955, Howland et al 1956), Italy (Dauri 1955, Taddei 1955), Sweden (Vinnars 1956), and in this country, where we have used it An identical compound has been studied in Scotland by Taylor and Shearer (1956) The structure of viadril and some other steroids is shown in fig 1

Our First 100 Cases

The 100 operations performed with viadril as the basic anæsthetic were

Laryngopharyngectomy (first stage)	2	Appendicectomy	3
Laryngopharyngectomy (second stage)	2	Prostatectomy	1
Partial gastrectomy	6	Partial nephrectomy	1
Partial thyroidectomy	6	Cholecystectomy	1
Œsophagectomy	2	Vulvectomy and bilateral inguinal adenectomy	1
Excision of rectum	3	Disarticulation of the hip	1
Excision of colon	3	Hypophysectomy	1
Hysterectomy	4	Subdiaphragmatic abscess	1
Colporrhaphy	5	Appendicular abscess	1
Radical mastectomy	4	Herniorrhaphy	2
Cystectomy of breast	2	Mastoidectomy	1
Bilateral adrenalectomy	2	Fissure in ano	1
Unilateral adrenalectomy	1	Sigmoidectomy	1
Oophorectomy and adrenalectomy	3	Diagnostic laryngoscopy	1
		Major dental operations	38

The accompanying table illustrates our use of viadril in a few of these 100 cases The first two operations in the table illustrate how the technique has been modified in the light of experience so that less viadril is now given and most of it is administered before and during the first few minutes of the operation

Method of Administration

Viadril was originally injected as a 2 5% solution into a fast running intravenous drip (Murphy 1955), but painful venous thrombosis followed in most cases Murphy et al (1955) reported only a 3% incidence of venous thrombosis, but we did not realise that their "fast running" drip was one which was pouring through the drip chamber like a running tap By trial and error, it was found that solutions weaker than 0 5% in physiological saline produced no vein troubles A suitable solution can most readily be prepared by dissolving five 500 mg vials of viadril in the usual 540 ml bottle of intravenous saline, however rapidly it is run in, this solution is trouble free, and causes no sclerosis of veins

With a drip rate of 150 per min the average patient becomes drowsy within 5 to 7 min and falls asleep in 10 min, although he can be roused by questioning or are at the disposal of even small hospitals Our future tasks are to look for methods of treating functional disturbances of the urinary tract and to prevent this dangerous and common disease This will be possible only after we have thoroughly recognised its cause, and this, especially in the primary form, still awaits a solution

I thank Dr D Benešova for the photomicrographs used in figs 1 and 19

'Idiopathic hypercalcæmia Is this the price we pay for the abolition of rickets ? —*Lancet* 1954, ii 128

In spite of the knowledge of the preventive action of vitamin D, and also of ultraviolet light rickets remains in the Baltimore community an extremely common disease '—E A Park (1953)

Two types of infantile hypercalcæmia have been recognised one with mental defect, often other congenital abnormalities, a long course, and a poor prognosis, and the other with no associated congenital defects, a shorter course, and usually a better prognosis (Schlesinger et al 1956) Most of the published cases have been of the latter type, and it is with this type that we deal here

Ætiology

Creery (1953) suggested that alkali therapy might be a contributory cause Lowe et al (1954) concluded, from a renal biopsy, that primary renal disease was probably not responsible They and others also dismissed primary parathyroid overactivity as a cause Idiopathic hypercalcæmia has not been reported in a wholly breast-fed infant, and this has been related to the fact that the calcium content of breast-milk is about a quarter of that of cow's milk (Creery and Neill 1954) The high phosphorus content of cow's milk is, however, held responsible for neonatal hypocalcæmia by other workers (Gardner et al 1950)

An abnormal sensitivity to normal doses of vitamin D has been suggested by Lightwood (1953) as the cause Such sensitivity and an excessive intake of vitamin D were considered as likely ætiological factors by Lowe et al (1954) and Creery and Neill (1954) Bonham Carter et al (1955) gave calciferol 10,000 units daily for eleven days to a child with idiopathic hypercalcæmia and, from the coincident clinical deterioration, concluded that there was an abnormal sensitivity to vitamin D The implication of these suggestions has led the British Pædiatric Association, at the instigation of the Ministry of Health, to conduct a national inquiry into the possible relationship between the intake of vitamin D and the development of idiopathic hypercalcæmia of infancy.

Certain objections can be raised against the concept of vitamin-D overdosage or hypersensitivity Very large doses of vitamin D have been tolerated in infancy without toxic effects, and Wolf (1943) concludes that there is a very wide margin of safety between optimal and toxic dosage

Creery and Neill (1954) state that 2 of their patients with idiopathic hypercalcæmia had had no supplement of vitamin D and a total intake of only 700 units of it daily They gave, in one of their active cases, 2000 units of calciferol daily for three and a half weeks and obtained a steady clinical improvement despite a transient rise in the serum-calcium level

Idiopathic hypercalcæmia has apparently not been reported from the United States of America (*Quarterly Review of Pediatrics* 1955)

An association has been reported between hypercalcæmia and interstitial plasma-cell pneumonia (Hallman et al 1954) This latter disease has only recently been recognised in this country (Baar 1955) During its acute phase the serum calcium level often rises, and in a few cases a raised serum-calcium level persists for weeks after the child has recovered.

Case-reports

The present study is based on 5 cases of idiopathic hypercalcæmia and a possible 6th case observed during 1951–56 The main clinical and biochemical findings and progress are given in tables I and II and figs 1–5

TABLE I—SUMMARIES OF CASE HISTORIES

Case no	Age at onset (mos)	Age when diagnosed (mos)	Duration of illness (mos)	Follow-up
1	3	7	7	Æt 3½ yr wt 39 lb ht 41 in, normal intelligence and activity serum Ca 12 0 mg per 100 ml plasma-cholesterol 185 mg per 100 ml

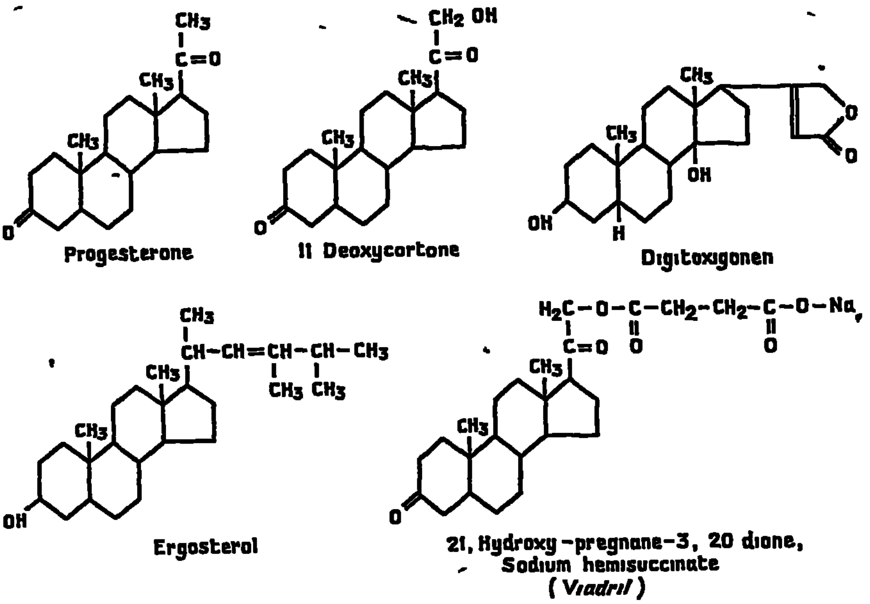

Fig 1—Structure of viadril and other steroids

touching the arm. After 15 min. he seems deeply asleep and cannot be roused by shouting or shaking, although he reacts to painful stimuli, in which respect viadril resembles intravenous bromethol ('Avertin'). At this stage a carefully inserted pharyngeal airway does not evoke the pharyngeal reflexes or cause laryngospasm. This is in striking contrast to thiobarbiturate anæsthesia, but resembles the chlorpromazine promethazine pethidine sequence ("lytic cocktail"). Laryngoscopy can also be performed, although there is slight resistance from the masseter muscles, and there may be slight but semi-purposeful limb movements. On the other hand, the vocal cords can be viewed with ease, they are wide apart and, when stimulated by touch, close and open again. This also is very different from barbiturate or thiobarbiturate anæsthesia when similar stimulation would not only send the vocal cords into spasm but produce a sphincteric closure of the proximal aperture of the glottis itself. Endotracheal intubation was sometimes possible under viadril anæsthesia alone, after which nitrous oxide and oxygen (5/2 mixture) was adequate to maintain anæsthesia for relatively simple procedures such as major dental surgery. More often, however, analgesics such as pethidine were added, and muscle relaxants as well, particularly for thoracic or abdominal surgery.

Hastening Induction

The usual induction period of 20–25 min. can be halved in the following way. Directly the patient falls asleep a mask can be held within an inch or so of the face and pure nitrous oxide administered. The mask is gradually lowered until it touches the face, when 20% oxygen is added to the mixture. After another 2 min., 30–50 mg. of pethidine is injected intravenously,* followed by a suitable dose of a muscle relaxant, in each case the doses are regulated according to circumstances in the usual way. After another minute the mask can be removed, laryngoscopy performed, and an endotracheal tube passed, nitrous oxide and oxygen are then given to maintain anæsthesia.

Electro encephalographic Changes

Steroid, barbiturate, and thiobarbiturate narcosis are indistinguishable so far as the electro-encephalograph (E.E.G.) is concerned. In each case, four arbitrary levels of anæsthesia can be distinguished by the E.E.G. (Bellville et al. 1956, Howland et al. 1956). After a few minutes of intravenous viadril the E.E.G. changes, and when the deepest level (level 4) is reached—i.e., when cortical activity has been fully suppressed—patients still move slightly when towel clips are applied. It is obvious, therefore, that cortical activity is suppressed before full surgical anæsthesia is is attained, and the E.E.G. seems to be useless for assessing the varying depths of surgical anæsthesia itself.

Respiration

Doses of viadril up to 2 g. do not appear greatly to affect either the depth or rate of respiration however rapidly they are given (fig. 2), although Howland et al. (1956) had occasional patients in whom tidal-volume was considerably diminished, and there was one who

---

* Pethidine, *d* tubocurarine chloride, and suxamethonium should not be injected into the viadril drip, since the first causes milkiness and the other two produce a flocculant precipitate when added to 0·5% viadril solution. Thiopentone, thialbutone, gallamine, atropine, neostigmine, nikethamide, nalorphine, and methylamphetamine are compatible with viadril.

EXAMPLES OF OPERATIONS PERFORMED WITH VIADRIL AS BASIC ANÆSTHETIC

Operation	Time *		Viadril (0·5%)			Adjuvants					Patient		
			Dose (mg.)	Time of infusion		Pethidine (mg.)	Muscle relaxant (mg.)	Tr	N₂O	O₂	Sex	Age	Condition
	hr	min		hr	min								
Laryngopharyngectomy	4	23	1560	4	29	50	Nil	Tr	N₂O	O₂	F	59	Fairly fit
Laryngopharyngectomy	5	5	1130		37	60	S M 50	Tr	N₂O	O₂	F	50	Fit
Œsophagectomy	2	46	1170		30	50	T C C 20		N₂O	O₂	F	60	Fairly fit
Œsophagectomy	3	21	1255		31	70	T C C 15		N₂O	O₂	F	72	Frail
Partial gastrectomy	1	27	1100		15	80	T C C 33		N₂O	O₂	M	49	Fit
Partial gastrectomy	1	39	975		40	90	T C C 35		N₂O	O₂	M	48	Fit
Perineal resection of rectum	1	9	1150	1	5	30	T C C 10		N₂O	O₂	M	79	Frail
Anterior resection—anastomosis of rectum	1	50	1250		25	70	T C C 33		N₂O	O₂	F	65	Fairly fit
Disarticulation of hip	2	28	1170		32	100	G 120		N₂O	O₂	F	50	Fit
Partial thyroidectomy	1	23	1000		22	30	T C C 10		N₂O	O₂	F	63	Thyrotoxic otherwise fit
Partial thyroidectomy	1	4	960		49	60	T C C 15		N₂O	O₂	F	47	Thyrotoxic and frail
Total colectomy	2	27	1470		32	90	T C C 20		N₂O	O₂	F	49	Ulcerative colitis, otherwise fit
Bilateral adrenalectomy	1	6	1170		33	70	T C C 15		N₂O	O	F	59	Diabetic otherwise fit

* Including induction of anæsthesia.
T C C = *d* tubocurarine chloride. G = gallamine ('Flaxedil'), S M = suxamethonium ('Scoline' 'Brevedil'). Tr = trichlorethylene in minimal concentration to settle coughing if head was moved or after tracheostomy and passing of sterile endotracheal tube.

TABLE II—BIOCHEMICAL FINDINGS

* Normal electrophoretic pattern † Increase in α' and β globulin

Case 1 —Male birth weight 9 lb 1 oz Breast fed for eight weeks, then given National dried milk (N D M) without additional vitamin supplement Normal progress for three months but thereafter vomited, lost weight, and became pale, anorexic, listless, and constipated

Admitted to hospital æt 5 mos Continued to vomit and required subcutaneous saline solution frequently Very ill when serum calcium level first estimated (12 7 mg per 100 ml) Improved two weeks later, when serum calcium level had risen to 15 2 mg per 100 ml Radiography showed increased peripheral density of metacarpal, tarsal, and metatarsal bones

Diet in hospital predominantly cow's milk except for period of low calcium diet (meat purée and sweetened fruit juice) No clinical improvement during latter diet although serum calcium level fell (fig 1)

Ultimately recovered satisfactorily, and three years later height and weight were well above normal for his age and at the 90th percentile of the values given by Mitchell Nelson (1950) for healthy children

Case 2 —Girl birth weight 7 lb 13 oz Breast fed for two weeks, then given N D M until weaned at one year Half a teaspoonful of cod liver oil daily until 3 mos old, thereafter no vitamin supplement until after onset of symptoms When 10 mos old vomiting, anorexia, constipation, loss of weight, pallor, and listlessness developed

Admitted to hospital æt 14 mos, underweight Characteristic radiological bone changes present Temporary spontaneous initial improvement followed by a relapse

Low calcium diet (as for case 1) given for three weeks Serum calcium level fell and clinical improvement took place and continued after reintroduction of a milk diet, although the serum calcium level rose to 16 1 mg per 100 ml (fig 2)

Discharged home after five months in hospital At the age of 3 years was considerably below the expected weight and height, at the 10th percentile and below the 3rd percentile respectively of the values given by Mitchell Nelson (1950)

Case 3 —Male identical twin of case 5 Birth weight 7 lb Breast fed for a month, then cow's milk Given cod liver oil a few drops a day in the early weeks, increasing progressively to a teaspoonful at 6 mos, when all vitamin supplements were stopped

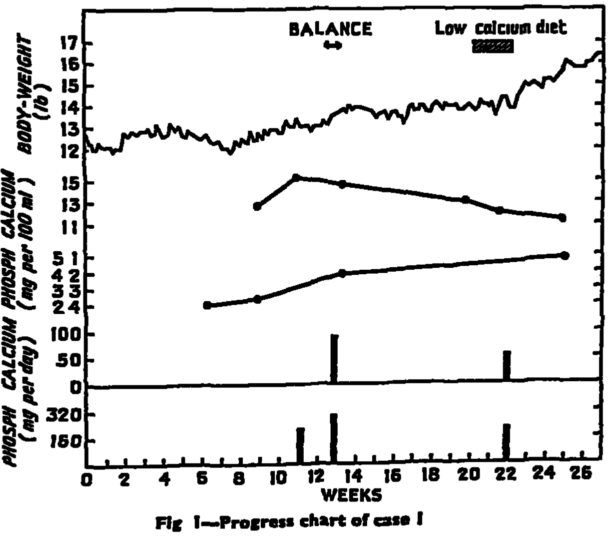

Fig 1—Progress chart of case 1

At 3 mos developed a respiratory infection treated with penicillin At $6^1/_2$ mos began to vomit and shortly thereafter developed an acute episode of vomiting and diarrhœa, which lasted five days Vomiting continued, and he gradually became constipated, pale, and apathetic

Admitted to hospital æt 8 mos, underweight and with continuing symptoms Some increased density of femoral metaphyses and periphery of tarsal bones

Began to recover after six weeks in hospital (fig 3) discharged after four months A year later below expected weight and height, at the 25th and the 10th percentile respectively (Mitchell Nelson 1950)

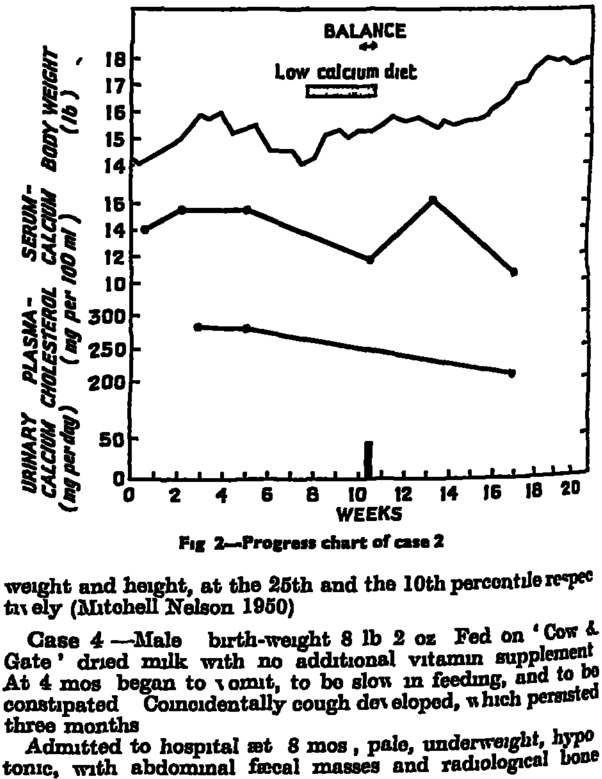

Fig 2—Progress chart of case 2

Case 4 —Male birth-weight 8 lb 2 oz Fed on 'Cow & Gate' dried milk with no additional vitamin supplement At 4 mos began to vomit, to be slow in feeding, and to be constipated Coincidentally cough developed, which persisted three months

Admitted to hospital æt 8 mos, pale, underweight, hypotonic, with abdominal fæcal masses and radiological bone changes of idiopathic hypercalcæmia

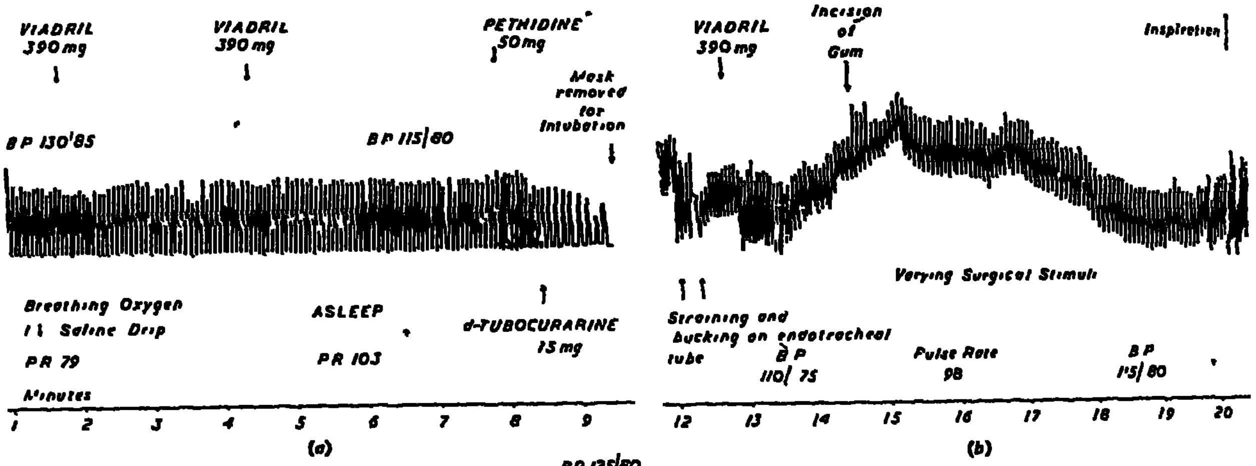
In hospital for five and a half months (fig 4)

At the age of 2 years very much underweight and underheight, at the 3rd percentiles (Mitchell Nelson 1950)

Case 5 —Identical twin of case 3 Birth weight 5 lb Breast fed for five weeks, then cow's milk Given cod liver oil a few drops a day in the early weeks, increasing to a teaspoonful at 6 mos and remaining at that amount At 6 mos respiratory infection developed At 9 mos given a ten day course of ultraviolet light At 10 mos vomiting anorexia, and loss of weight developed, with initially a four day episode of diarrhœa, then constipation

Admitted to hospital a fortnight after onset of symptoms Began to recover after three weeks

This child's illness was very similar in onset and symptoms to that of his twin His mother and the family doctor considered the illnesses to be the same The



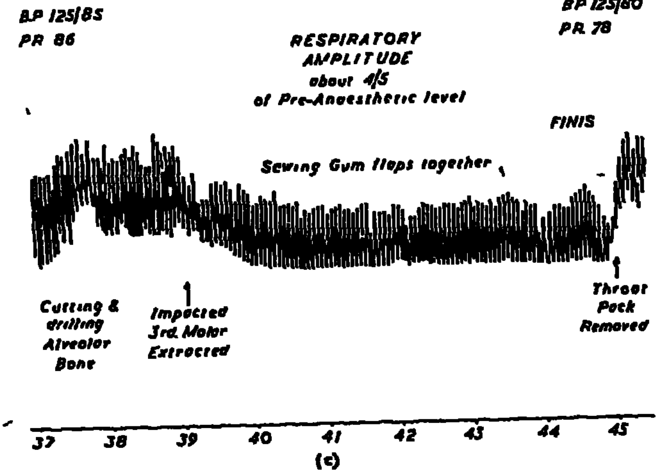


Fig 2—Respiratory tracing during removal of impacted 3rd molar in woman of 29

(a) Viadril (2·5% solution) and other drugs injected into intravenous saline drip On each occasion 390 mg of viadril was injected in two minutes

(b) Transnasal endotracheal intubation 3 min before this part of tracing N_2O and O_2 via tube

(c) Endotracheal N_2O and O_2 continuing (CO_2 absorption)

required artificial respiration for 30 min It may be significant that these patients were all "general surgical patients admitted to a hospital for neoplastic diseases," and many were, presumably, toxic and elderly subjects When controlled respiration is attempted, we agree with Murphy et al (1955) that respiration is more easily "taken over" than it is with thiobarbiturate anæsthesia For instance, during an abdominothoracic œsophagectomy, using 1225 mg of viadril and lasting 3 hours 21 min, controlled respiration was easily maintained under nitrous oxide and oxygen, with the addition of 50 mg of intravenous pethidine and a dose of *d* tubocurarine chloride as small as 15 mg (the entire dose of tubocurarine was given before endotracheal intubation)

Reflexes

As we mentioned, the pharyngeal reflex is soon suppressed—i e, when 500–600 mg of viadril have been given At this stage, also, there is no laryngospasm when the vocal cords are stimulated, although their momentary closure suggests that they have preserved their sensitivity After intubation, the endotracheal tube is more easily tolerated than it is under thiobarbiturate anæsthesia Even when anæsthesia is extremely light, movement of the tube rarely produces more than a few seconds breath holding there is a remarkable absence of the "bucking" so common under all other forms of anæsthesia Again, bronchospasm is rare Controlled respiration is easy, perhaps because of facilitation of the mechanism whereby the respiratory centre is depressed by continued rhythmic inflation of the lungs When surgical anæsthesia is attained, the pupils are small and no longer react to light

Circulation

We agree with Taylor and Shearer (1956) that the pulse rate is very much higher than is usual under other forms of intravenous anæsthesia, although we cannot entirely agree that this is due to the fact that viadril i more of a hypnotic than an anæsthetic Were this view entirely correct, one would expect the pulse rate to be rapid only during surgical stimulation whereas rates of 85–105 per min have been noted during induction, even when the infusion rate was slow On the other hand, intravenous pethidine, a known analgesic, has significantly reduced the pulse-rate during the actual operation Another unusual feature, which makes it hard to be dogmatic about the absence of analgesic properties, i the fact that painful stimuli, which would appreciabl increase the rate and amplitude of respiration during thiobarbiturate anæsthesia, have little or no effect during steroid anæsthesia, despite a relatively high pulse rate Moreover, even during exceedingly painful procedure the respiratory-rate has remained steady at rates of from 14 to 26 per min

Sharp falls of blood-pressure have occasionally been noted but we did not find that they were confined to elderly subject (Taylor and Sheare 1956) In ou experience th blood pressure al falls in youn people, though les often than in th old (fig 3) Suc falls are much les likely if the dru is administere slowly—i e, 60-10 drops per min— but unfortunatel this slows a already tard induction

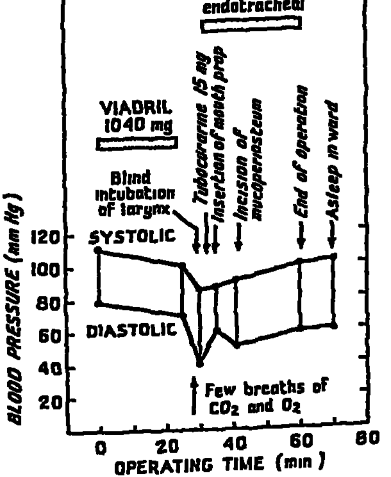

Fig 3—Fall of blood pressure during extraction of impacted upper and lower 3rd molars in woman of 30 Spontaneous recovery

Muscles

Owing no doub to the fact that w supplemente viadril directly th patient fell aslee we have not see plasma cholesterol level as with his brother was raised It appears quite likely that he had the same disease as his brother but presenting in a milder form

The criteria of identical twinning were as follows they looked alike, the blood-groups, including A B O, Rh phenotype, and probable genotype, M N S and P, Lutheran, Kell, Lewis a and b, and Duffy, were identical, blood from both parents and the four other siblings examined in the same way showed that the probability of uniovularity was at least 98 7%, calculated by the method of Race and Sanger (1954) The finger prints, according to the criteria of Cummins and Midlo (1943) were compatible

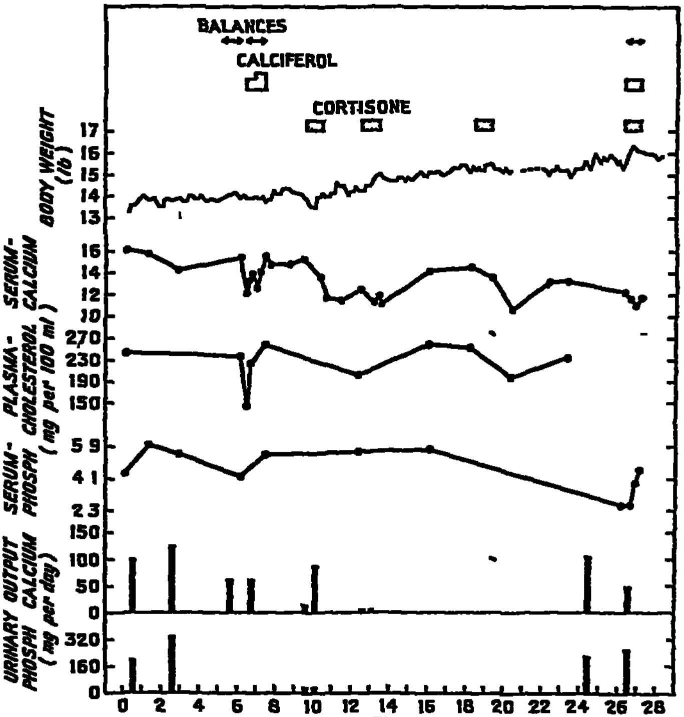

Fig 4—Progress chart of case 4

Case 6.—Girl birth weight 8 lb 12 oz Breast fed for two months then Cow & Gate milk Half a teaspoonful of cod liver oil at 2 mos, increasing to 1 teaspoonful at 3½ mos and remaining at that level 'Farex' at 4½ mos Given 'Glucose D' (1 or 2 teaspoonfuls daily) from 3 mos onwards At 5½ mos cough (which lasted a month), vomiting and constipation loss of weight, and anorexia developed

Admitted to hospital at 7 mos (fig 5) Palpable fæcal masses hypotonia and suggestive radiological changes in bones

Method

The balance periods lasted five to eight days except for the three-day balance on a low calcium diet With milk feeding an aliquot from each day's feed was kept and analysed Where a mixed diet was being given each feed was duplicated and the pooled duplicates for the day analysed Apart from case 1 when re examined at the age of 3½ years and case 2 when on a low calcium diet, the balance diet consisted of cow's milk with additional cornflour and arrow-root occasionally All the infants had been on the balance diet for at least four days before the balance studies were begun, and, except in case 6, no vitamin supplements had been given for several weeks or months previously Urine and fæces were collected daily by the methods described by Forfar and Prain (1950) Specimens for the estimation of daily urinary excretion of calcium and phosphorus were usually collected over several consecutive days

Standard biochemical methods were used Fæces and diet were emulsified with water to a convenient volume in an 'Ato mixer,' and an aliquot was examined

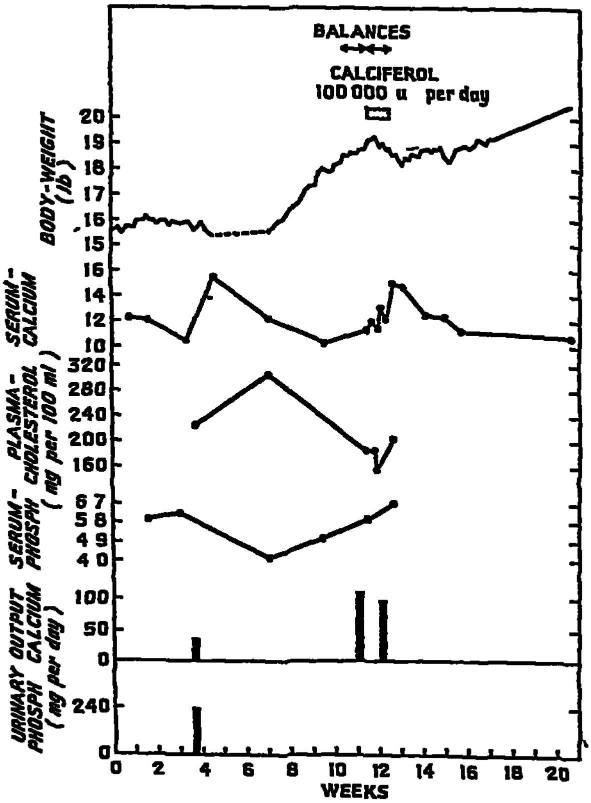

Fig 3—Progress chart of case 3

Intake of Vitamin D and Effect of Calciferol

The approximate intake of vitamin D in these cases and the form in which it was predominantly administered are shown in table III The figures are calculated on the assumption that a teaspoonful of cod-liver oil contains 700 units of vitamin D, a level scoopful of National dried milk powder 40 units, of proprietary milk powder 45 units, and cereals the amounts stated by the manufacturers

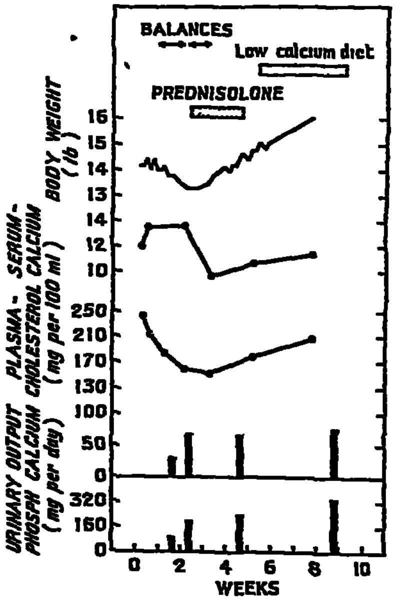

Fig 5—Progress chart of case 6

Since cases 3, 5, and (to a lesser extent) 1 had had low intakes of vitamin D, it was felt that this vitamin might twitching or rigidity of the limbs during induction (Taylor and Shearer 1956). Often, however, there was a clonic convulsive rigidity—sometimes accompanied by generalised trembling—at the end of the operation, after stopping nitrous oxide and oxygen. This usually resolved spontaneously within 1–2 min. The muscles of the limbs, neck, and trunk were involved, and the respiratory movements were not being greatly impeded.

Although controlled respiration can be instituted after small doses of muscle relaxants, the conventional doses are necessary if full muscular relaxation is required for abdominal surgery.

After-effects

We have been greatly impressed by the absence of after-effects. Only 1 of our patients has vomited during the recovery period and no others have had any nausea. The recovery times after viadril seem to be slightly shorter than we would have expected had thiopentone been the main anæsthetic.

Postoperative fatigue is greatly reduced, even compared with other forms of intravenous anæsthesia. So interesting were these findings that a comparison was made between two series of major dental operations (60 cases in all): half had thiopentone as the basic anæsthetic and the other half viadril. Those who had thiopentone all felt slightly lethargic the next day, they lacked appetite, and a few felt slightly sick. Those who had viadril were all alert, and anxious to get home, and they ate as ravenously as their dental disabilities allowed.

One young woman had two similar and symmetrical operations within a fortnight, one with thiopentone and the other with viadril. In each case pethidine was avoided during anæsthesia and the doses of suxamethonium before intubation were identical. The length of the operations was much the same (just over an hour) and a nitrous oxide/oxygen mixture (5:2) was used for maintenance. Quite spontaneously, this patient said she felt "very much better" after viadril than she did after thiopentone.

Even more remarkable was the lack of postoperative fatigue and the sense of well-being of patients undergoing major surgery.

22 hours after an abdomino perineal resection of his rectum a patient carried on an interesting conversation and said that he felt better after viadril than after three other operations (appendicectomy, herniorrhaphy, and sigmoidoscopy) all under thiopentone, *d*-tubocurarine, and/or pethidine. 26 hours after an œsophagectomy a middle-aged woman was knitting an intricately designed bed-jacket. Both these patients seemed to have the same attitude towards their pain as if they had just had chlorpromazine.

Discussion

It is interesting to compare viadril with thiopentone. By and large, viadril seems capable of replacing thiopentone (or similar thiobarbiturates) in any anæsthetic sequence. It suffers, however, from the fact that it has to be given in a very dilute solution to avoid venous sclerosis, and it is, therefore, unlikely to replace thiopentone for short operations when the induction period might greatly exceed the operating-time and appreciably prolong the operating session. Owing to the rapid suppression of the pharyngeal and laryngeal reflexes, this disability can be overlooked if smooth anæsthesia is desired for laryngoscopy, or for the opening of a submandibular cellulitis. We have been particularly impressed with viadril for thyroid surgery. Not only is there less likelihood of "bucking" on the endotracheal tube as the larynx is unavoidably moved during the operation, but the docility of the throat reflexes means that direct laryngoscopy can be performed with the greatest ease at the end of the operation for evidence (or otherwise) of recurrent laryngeal palsy. In major surgery, where intravenous infusions are almost inevitable, viadril probably comes into its own, particularly since it secures so smooth and pleasant a recovery.

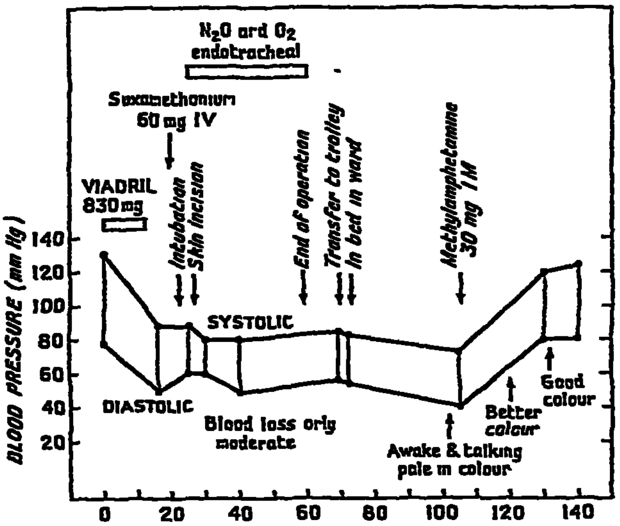

Fig. 4—Effect of intramuscular methylamphetamine on postoperative fall of blood pressure after excision of cyst of breast in a woman of 46.

The occasional falls in blood-pressure are not so alarming as they sound. In every case the patient's appearance and pulse volume was so good that the actual blood-pressure level surprised those recording it. Unlike "hypotensive anæsthesia" (with pentamethonium or hexamethonium or 'Arfonad') there seemed to be no venous engorgement of the limbs, and postural ischæmia was difficult to obtain. Methylamphetamine or similar drugs, given intravenously or intramuscularly, never failed to rectify any fall in blood-pressure (fig. 4).

As for the lack or diminution of postoperative fatigue, viadril resembles the chlorpromazine-promethazine-pethidine sequence ('lytic cocktail'). Viadril, however, has the advantage that after they return to the ward patients rarely have any fall of blood-pressure and, if they do, it can readily be restored by intramuscular methylamphetamine.

Why patients feel so fit after viadril is unknown. It may well be that the drug inhibits the excretion of adrenocorticotrophic steroids during the actual operation, and that they are thus preserved to cope with the stress of the recovery period. Alternatively, this sense of well-being may be similar to that of cortisone or corticotrophin (A.C.T.H.) therapy—the cause of which is also unknown. In this respect it is interesting to note that Hoeffer and Glaser (1950) demonstrated E.E.G. changes suggestive of cortical suppression in patients who had had corticotrophin for three to five days. We intend to take E.E.G.s during their recovery from viadril to ascertain whether they demonstrate similar findings.

Not the least interesting facet of steroid anæsthesia is the light it may throw on the rhythmic causation of sleep. It is now generally agreed that the normal state of the cerebral cortex is one of inactivity or sleep and that wakefulness is maintained only by a continual bombardment of impulses from the reticulo-activating centre of grey matter situated in the brainstem. In turn this centre is activated by centripetal impulses from the entire sensory system. Barbiturate, thiobarbiturate, and steroid anæsthesia may be regarded as depressing this reticulo-activating centre so that it no longer stimulates the cortex into wakefulness and unconsciousness supervenes. This hypothesis does not, however, explain the rhythm of sleep or the increased and overwhelming desire for sleep after long periods of wakefulness. 19th-century

TABLE III—APPROXIMATE INTAKE OF VITAMIN D BEFORE ONSET OF SYMPTOMS, AND TYPE OF VITAMIN D ADMINISTERED

Case no	Range (units)	Average daily intake (units)	Average daily intake for a month before onset of symptoms (units)	Form in which vitamin D was predominantly given
1	45–1300	550	1250	D
2	30–2000	1350	1950	D_2 and D_3
3	30–750	400	400	D_2
4	750–1500	1200	1450	D_2
5	20–760	570	750	D_2
6	33–2500	1240	2300	D_2 and D_3

have been too readily incriminated as a possible cause of idiopathic hypercalcæmia Vitamin D is stated to increase the urinary excretion of calcium by decreasing tubular reabsorption (Dent 1954) It is generally agreed that it favours the deposition of calcium in the bones Therefore, in infantile hypercalcæmia, in which the metabolism of calcium is already disturbed, the administration of additional vitamin D might be beneficial in that, under its influence, the urinary excretion of calcium and the deposition of calcium in the bones might be increased at a relatively greater rate than the alimentary absorption of calcium The work of Bonham Carter et al (1955) had not been reported at this time Pure calciferol (vitamin D_2) 50,000–100,000 units a day was therefore given by mouth to cases 3 and 4 Case 3 had a slight temporary loss of weight (fig 3), but such fluctuations in weight are common in infantile hypercalcæmia (figs 1 and 2) and this fall may have been fortuitous The serum-calcium level rose by 3 5 mg per 100 ml but quickly fell again—a similar effect to that reported by Creery and Neill (1954) The level reached, however, was lower than that which had previously been reached spontaneously Otherwise no beneficial or adverse effects were noted either during therapy or during the following eight months In case 4 there was no clinical change during or after calciferol therapy The serum calcium level fell by 3 1 mg per 100 ml and returned to its previous height the day after calciferol was discontinued Comparable normal controls given the same dosage of calciferol showed rises of 1 2 and 0 7 mg per 100 ml in 2 cases and a fall of 1 0 mg per 100 ml in 1 other

Calciferol was also given to case 1, who had been free from symptoms, had had no vitamin-D supplement for more than two years, and had a normal serum calcium level Again neither immediate nor long-term effect were noted There was no change in the serum calcium level The biological activity of the batch of calciferol used was proved by curing a case of active rickets with it

Calcium-balance Studies

The nature of the balances, the stage of the disease at which they were studied, and the results are shown in table IV

Unrestricted Diet No Vitamin-D Supplement or Vitamin D-fortified Milk

The retention of calcium was 31%, 48%, and 69% in the active cases, 16% in the recovering case, and 16% in the cured case

A very wide range of retention of calcium has been found in healthy infants on a milk diet From the work of Hoobler (1911), Telfer (1922), Daniels and Stearns (1925), Flood (1926), Stearns (1933), Jeans et al (1936), and Harrison (1936) we have obtained the results of 24 calcium balances studied in healthy infants aged 7–12 months and fed on a cow's milk diet or an evaporated milk diet with, so far as can be ascertained, a normal intake of vitamin D On an average intake of 1 17 g of calcium daily the mean retention of calcium was 32% or 0 38 g (range 0–79%) which agrees very closely with the daily

TABLE IV—CALCIUM AND PHOSPHORUS BALANCES

Balance	Case no	Age (yr)	Clinical state	Duration of balance (days)	Average daily intake (g)	Average daily output (g)		Retention	
						Fæces	Urine	Amount (g)	% of intake
Calcium Normal diet	1	8/12	Active	5	1 500	0 940	0 090	0 470	31
	4	9/12	Active	7	0 896	0 404	0 063	0 429	48

	6	7/12	Active	6	0 319	0 056	0 083	0 180	56
Normal diet plus prednisolone 5 mg daily	6	7/12	Active	6	0 412	0 248		0 164	40

* Calciferol 50 000 units daily for first 3½ days of balance

physiologists used to postulate a "hypnotoxin"—i e, a noxious chemical agent accumulating in the brain "which when present in sufficiently high concentrations arrests cerebral activity which does not recover again till the alleged toxin is destroyed" (Wright 1952) Alternatively, it might be (Kalmus 1956) that an as yet unidentified steroid is secreted during the stress and fatigue associated with wakeful activity, which builds up to a sufficiently high concentration to suppress the reticulo-activating centre which, in turn, can no longer activate the cortex, so that sleep ensues ?

Summary

Viadril is the first steroid to be used in human anæsthesia and is the first departure from the derivatives of barbituric and thiobarbituric acids since intravenous anæsthesia became established in 1932 Judging from animal experiments, its therapeutic index (i e, the ratio between the dose producing apnœa and the dose causing death during artificial respiration) is much greater than any barbiturate or thiobarbiturate in clinical use as an anæsthetic

In contrast to all the ultra short-acting barbiturates and thiobarbiturates, viadril rapidly suppresses the pharyngeal and laryngeal reflexes, even under the lightest narcosis it is difficult to provoke vomiting or laryngospasm

Falls of blood pressure and a rise in pulse rate are more frequent with viadril than with thiobarbiturate anæsthesia With viadril, however, the lowering of blood-pressure often rectifies itself and, if it does not, it can readily be remedied by intramuscular or intravenous methylamphetamine or similar drugs

Vomiting is rare after viadril anæsthesia, post-operative fatigue is slight or absent and patients experience a sense of well-being during their recovery from operation similar to that produced by cortisone

In concentrations greater than 0 5%, viadril solutions unfortunately give rise to painful venous thrombosis, it must therefore be given as an intravenous drip and, consequently, the induction period is long This will probably limit the drug's use in the shorter operations For long operations, where an intravenous drip is almost inevitable, viadril causes less inconvenience from the point of view of time and may well prove the anæsthetic of choice

Whether used alone or in place of thiopentone in the usual hypnotic analgesic muscle relaxant sequence, viadril not only offers ideal operating conditions but ensures a more comfortable recovery period than any other anæsthetic or anæsthetic combination in common use

'Viadril' was kindly supplied by Pfizer Ltd

LIVER PREGNANCY

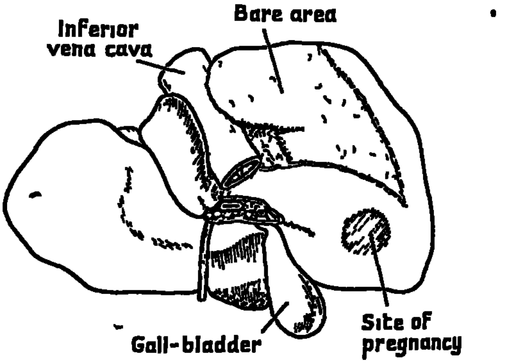
A H G MURLEY
M B Lond, F R C S
FORMERLY SURGICAL REGISTRAR, ROYAL PORTSMOUTH HOSPITAL, HANTS

IN most extra-uterine pregnancies the abnormal placental site is in the pelvis Cornell and Lash (1933) found records of 236 pregnancies involving placental attachment to 641 sites, the great majority being in the pelvis In 8 cases one site of attachment was the liver but note was not made whether this was ever the sole area Echols (1934) and Barrett (1952) mentioned patients in whom the placental site involved several organs, one of which was the liver Billington and Goodchild (1948), Serebriakova and Kanshin (1952), and Van de Loo (1953) described placental sites solely in the liver The following is another example of this rare condition

Case-report

A woman, aged 39, was admitted to the Royal Portsmouth Hospital at 6 A M on May 19, 1955 At 10 P M on the previous evening very severe pain began suddenly in the right hypochondrium The pain became generalised in the abdomen and was referred to the left shoulder and the back The patient was nauseated but did not vomit and passed no urine, fæces, or flatus Before this illness her health had been good except for a miscarriage in 1945 She had three children aged 9, 3, and 2 years She said that her appetite had been abnormally good in the previous two weeks but that she had some epigastric discomfort immediately after food Micturition and bowel habit had been normal, and she had no abnormal respiratory or cardiovascular symptoms Menstruation had been regular, lasting 4 or 5 days in each cycle of 27 or 28 days The loss had tended to increase in recent years, and there was a slight offensive intermenstrual vaginal discharge The last period of menstruation was from April 25 to April 29, 1955

On admission the patient was shocked and in pain Her tongue was dry and furred Her chest was normal on clinical examination Her abdomen was completely rigid and tender all over and on rectal palpation of the pouch of Douglas, but especially in the right hypochondrium Bowel sounds were absent Perforated peptic ulcer was diagnosed and laparotomy was done at 9 A M on the day of admission



Posterior and inferior surfaces of liver, showing site of pregnancy

Operation—A small upper paramedian incision revealed dark blood in the peritoneal cavity Four pints of blood and peritoneal exudate was removed during the operation No cause was found in the upper abdominal organs palpable through the original incision, and the uterus was felt to be enlarged, with tumours on each side of it, the pelvis contained much blood A lower abdominal paramedian incision showed that each ovary contained several small cysts and that the uterus was enlarged by fibroids The cysts were removed, and the search for the origin of the bleeding was continued by enlarging the upper incision Fresh bleeding was detected coming from the posterior surface of the liver normally in relation to the right kidney (see figure), it came retention of calcium in a similar age group reported by Sherman and Hawley (1922) from their study of German published reports, and with the calculated requirement of the body at this age (Leitch 1937).

In our 3 active cases the mean intake of calcium was 1.02 g. a day and the mean retention 49% (0.45 g.) a day.

In view of the wide range of retention in healthy infants and even in the same infant, of the anorexia, vomiting, and constipation which make balance studies in idiopathic hypercalcæmia difficult, and of the variety of other factors which can influence the retention of calcium, individual calcium balances or small series of balances must obviously be interpreted with caution. We feel, however, that the retention of calcium in these cases, especially when considered along with the increased urinary excretion of calcium, the raised serum-calcium level, and the probably increased deposition of calcium in the bones, indicates increased absorption of calcium from the alimentary tract.

Unrestricted Diet with Additional Prednisolone

In case 6 this balance was studied in the early acute phase of the disease. Under the influence of prednisolone, 5 mg. a day, a positive calcium balance of 69%, with an average daily retention of 0.45 g., was converted to a balance of 46%, with an average retention of 0.37 g.

Unrestricted Diet with Additional Calciferol

The retention of calcium was increased in all the cases by calciferol—to 73% in the active case, 40% in the early recovery case, and 42% in the inactive case.

Honet (1946) gave a single dose of calciferol 600,000 units to a healthy infant, aged 6 months, whose retention of calcium just before the calciferol was given was 45%. Over consecutive ensuing three-day periods retentions of 67%, 47%, 70%, and 45% were observed. Previous deprivation of vitamin D also increases sensitivity (Honet 1946)—a relevant factor in our cases.

Thus calciferol caused no significant clinical change and did not appear to increase the retention of calcium to a greater degree than might have occurred in a healthy infant.

Unrestricted Diet with Additional Calciferol and Cortisone

In case 4 the balance was studied four months after the previous (calciferol) balance. The retention of calcium was 25%, which is considerably less than the retention on the same dosage of calciferol alone, and considerably less than the retention in the first study, when no calciferol supplement was given.

Low-calcium Diet

The infant had been on a low calcium diet for eighteen days before the balance was studied. A negative calcium balance resulted and, as was found by Ferguson and McGowan (1954), Russell and Young (1954), and Bonham Carter et al. (1955), there was a fall in the serum-calcium level.

Urinary Excretion of Calcium

On a normal diet without added vitamin D the daily urinary excretion of calcium (eight estimations) was 30–127 mg. (mean 83 mg.). In healthy infants of the same age on about the same intake of calcium the range of eighteen estimations published by the workers already cited above was 8–55 mg. (mean 27 mg.) of urinary calcium a day. Knapp (1947) reported 3–86 mg. a day.

In idiopathic hypercalcæmia ranges of 23–122 (mean 69) mg. a day (Lowe et al. 1954), 40–67 (mean 53) mg. a day (Creery and Neill 1954), and 34–128 (mean 82) mg. a day (Bonham Carter et al. 1955) have been reported. Thus although there is a wide individual and case-to case variation, there appears to be little doubt that hypercalcuria occurs in idiopathic hypercalcæmia of infancy.

A feature of the present study is that (with the special exception of case 1 after recovery) calciferol in the dosage given did not increase the urinary output of calcium. Dent (1954) suggests that vitamin D reduces the tubular reabsorption of calcium, thus increasing its urinary excretion. Honet (1946) has shown that in healthy infants, a dosage of calciferol comparable to that given to our patients slightly increases the urinary excretion of calcium. Accentuation of this effect might be expected in the presence of vitamin-D hypersensitivity. The failure of calciferol to increase further the hypercalcuria which was already present in the affected cases cannot be attributed to incapacity of the kidney to excrete more calcium, no matter how high the intake of calciferol might be, because in case 4, a month previously, spontaneous urinary outputs of calcium considerably in excess of that obtained with calciferol were observed (fig. 4).

Thus, although there is moderate hypercalcuria in idiopathic hypercalcæmia, there is no renal response to calciferol.

At the age of 3½ years case 1 showed more than a twofold increase in the urinary output of calcium in response to calciferol. Clinically he had long since recovered from idiopathic hypercalcæmia, and his response to calciferol was probably normal and a function of his age rather than his disease. Knapp (1947) has shown that healthy infants excrete in their urine a smaller proportion of their intake of calcium than do older children and adults, and that it is about the age of 2 years that the adult pattern of excretion is attained.

Phosphorus Metabolism

Phosphorus balances were studied in cases 1 and 6 on normal milk diet during the active phase of hypercalcæmia (table IV). The retention of phosphorus was 40% and 56% respectively.

In 24 published phosphorus balances studied in healthy infants aged 7–12 months having, so far as can be ascertained, a normal intake of vitamin D (Blauberg 1911, Hoobler 1911, Telfer 1922, Daniels and Stearns 1925, Stearns 1933, Jeans et al. 1936, Harrison 1936) the mean intake of phosphorus was 0.89 g. a day, and the mean retention 23% (0.20 g.) a day.

In our 2 active cases the mean intake of phosphorus was 0.91 g. a day and the mean retention 43% (0.39 g.) a day. There thus appears to be an increased retention of phosphorus in idiopathic hypercalcæmia. Honet (1946) has shown that the effect of calciferol on infants is to reduce the retention of phosphorus somewhat.

Random estimations of daily urinary excretion of phosphorus on a milk diet without added vitamins were made on seven occasions. The range was 85–324 mg. (mean 229 mg.) a day. In the above mentioned published balances the mean daily output of phosphorus in the urine was 437 mg. on a roughly comparable intake of phosphorus. In the cases of idiopathic hypercalcæmia there was thus a hypophosphaturia. In infancy calciferol normally causes hyperphosphaturia (Honet 1946, Fanconi and de Chastonay 1950), which might be expected in idiopathic hypercalcæmia if increased susceptibility to vitamin D were present.

Seventeen estimations of serum-phosphorus levels were made in these cases on a standard cow's-milk diet without added vitamin D. As observed by other workers, the levels fluctuated widely. The range was 2.4–6.3 mg. per 100 ml. (mean 4.9 mg. per 100 ml.) in contrast to the normal range of 4.5–5.7 mg. per 100 ml. (mean 5.4 mg. per 100 ml.) for children of this age (Bullock 1930). In hypervitaminosis D in infancy the serum-phosphorus level has been reported to be lowered (Fanconi and de Chastonay 1950) and to be raised (Jelke 1946, Ross 1952).

The serum-calcium and serum-phosphorus levels were estimated together on twenty occasions. The correlation coefficient was -0.08, thus no correlation between these could be demonstrated.

from a soft globular tumour 3 cm in diameter The tumour was enucleated with ease and the bleeding from the resulting cavity in the liver was controlled by packing the cavity with Oxycel' gauze The wounds were closed without drainage Four bottles of blood were given during the operation and the postoperative recovery was uneventful Histological examination of the tumour showed a collection of chorionic villi and highly active trophoblastic tissue

Follow up—When seen six months later the patient was in good health

I wish to thank Mr Bernard Williams for permission to publish and Dr H. Miller for the histological report

A TRANSFUSION ACCIDENT

S VARADI
M.D. Prague
CONSULTANT HÆMATOLOGIST

J G VACCARO
M.B Lond
REGISTRAR IN PATHOLOGY

CITY GENERAL HOSPITAL SHEFFIELD

On May 16, 1955, a woman, aged 27 aborted and a few hours later was transfused with two bottles of ABO incompatible blood The error was discovered four hours after the transfusion had been completed, and the only early sign of a hæmolytic reaction was the secretion of black urine, discovered when the patient was catheterised before operation She was immediately placed on the Bull regime she developed oliguria, nitrogen retention (blood-urea level 75 mg per 100 ml.) jaundice (bilirubin 9 2 mg per 100 ml), and inadequate circulation (pulse-rate 150, blood-pressure 85/60 mm Hg) After 54 hours she vomited and diarrhœa developed , so the strict Bull regime had to be abandoned and feeding by mouth begun , but next day, 72 hours after the transfusion diuresis set in and she thereafter made an uninterrupted recovery and was discharged on May 31

The disappearance of the transfused cells was followed by Ashby's differential-agglutination method free circulating anti-A was detected by agglutination of A cells by the recipient s serum, and anti-A adsorbed on recipient's cells by the direct anti-globulin method The results are shown in the accompanying table

Date in May	Direct anti-globulin test	Presence of B cells (Ashby)	Presence of anti A	Volume of urine (ml)
17	++	Not tested	Not tested	50
18	++	Not tested	Not tested	500
19	++	+	+	230
20	++	0	+	360
21	++	0	+	460
23	0	Not tested	0	1020

It is clear that foreign incompatible agglutinins derived from donor plasma remained in the recipient s bloodstream even longer than did the foreign red cells

Technique

The patient had been admitted on May 11 and next day was grouped by the hospital blood bank as group B rhesus positive the cells being tested against known serum and the patient's serum tested with known cells When the duty pathologist was asked for blood he did not check the patient s group but took two bottles of group-B rhesus-positive blood from the store for cross-matching by the tube-centrifuge method Agglutination took place in both tubes The pathologist took two more bottles of group-B rhesus-positive blood and repeated the test this time setting up a control with the patient's cells in her own serum , all the tubes showed agglutination, which he ascribed to an auto-agglutinin active at 37°C, although such auto-agglutinins are very rare whereas errors in ABO grouping and non-specific clumping by centrifuging at too high a speed are fairly common

The pathologist then set up a routine cross-match in saline solution and albumin, both at 37°C, and set up cells and serum for the anti-globulin test using the patient s cells in her own serum as an indicator for auto-agglutinins However when he visited the ward he concluded that the patient's clinical state warranted immediate transfusion , so after an hour s incubation he read the saline solution cross-match, which showed no agglutination and completed the anti-globulin test, which was also read as negative He then issued the blood

The blood was administered between 4 45 A M and 10 A M on May 17 and caused neither dyspnœa backache, nor rigor the incompatibility was discovered at 2 15 P M , when the blood-bank staff checked all the night emergency work It became clear that the patient s group was A and not B, and that the blood-bank staff had made an error on May 12 The original serum which had been kept was found to contain anti-B , so it must have come from a patient of group A No explanation for this error could be found

The cross-match had failed to demonstrate the error without ambiguity When it was repeated with sera collected on May 12 and 17 against a 2% suspension of donor cells at room-temperature, there was strong agglutination, with a trace of hæmolysis only, but at 37°C there was well-marked hæmolysis in both tubes, and the residual cells were uniformly distributed except for a few clumps Further tests with added guineapig complement showed that an anti-B hæmolysin active at 37°C was present in both samples of serum, causing almost complete hæmolysis at a titre of 1 and a trace at 4 whereas at room-temperature there was only a trace at 1 There was nothing to suggest an immune origin for this hæmolysin A sample collected ten days after transfusion showed a hæmolysin titre of 16 and an agglutinin titre of 256 compared with a pre-transfusion value of 32.

Comments

This incompatible transfusion occurred because

(1) The technical staff of the bank made an error in ABO grouping

(2) The duty pathologist believed the bank s result and did not check it even when he got unexpected results

(3) He set up the saline solution cross match at 37 C instead of at room temperature and did not recognise the hæmolysis

It follows that

(1) Since auto agglutinins active at 37°C are very rare if their aid must be invoked to explain the results of cross-matching tests a gross error has probably been made

(2) The most probable error in such a case is an error in ABO grouping usually of the recipient This can be checked on the tile in a few minutes If the recipient s ABO group is correct. that of the donor should be checked. with special attention to the possibility of A_2.

(3) Hæmolysis in a cross match usually indicates an ABO incompatibility this can be confirmed by a slide test or more slowly by a saline solution test at room-temperature

(4) The saline-solution cross match should be kept at room-temperature where it will easily identify anti-A anti-B anti M, anti H, and anti-P it should not be incubated at 37 C, where hæmolysins may be active

We wish to thank Dr W J Clancy and his staff for their full coöperation and Dr George Discombe for his invaluable help throughout

The serum alkaline phosphatase level tended to be low, as in vitamin-D intoxication (Fanconi and de Chastonay 1950)

Prednisolone, 5 mg a day, converted a positive phosphorus balance of 59%, with an average daily retention of 0 18 g, to a balance of 40%, with a retention of 0 16 g

Citrate Metabolism

Serum citrate levels and urinary outputs of citrate were estimated in case 6 in the active phase and in cases 4 and 6 during recovery In the active phase the serum citrate level was 0 7 mg per 100 ml, and during recovery 1 8, 2 4, 2 5, and 1 8 mg per 100 ml on four occasions Harrison and Harrison (1952) have given the mean serum citrate level in infants aged from 2 months to 2 years as 2 5 mg per 100 ml, with a range of 2 0–3 4 mg per 100 ml Thus the serum-citrate level was low in the active phase and gave no indication of increased vitamin-D effect in which raised levels up to 6 mg per 100 ml may be obtained (Harrison 1954)

The twenty four-hour urinary output of citrate in the active phase was 9 5 mg and 10 6 mg on two occasions and in the recovery phase 96 mg The output in the active phase was low and that in the recovery phase low normal in contrast to the high urinary output of citrate in hypervitaminosis D

Cholesterol Metabolism

Hypercholesterolæmia was a feature of cases 2, 3, 4, and 6 Cholesterol was not estimated in case 1 Lowe et al (1954), Creery and Neill (1954), Dawson et al (1954), and Macdonald and Stapleton (1955) have all reported hypercholesterolæmia in idiopathic hypercalcæmia Vitamin-D intoxication in infancy has been reported with either a low or a normal plasma cholesterol level (Jelke 1946, Fanconi and de Chastonay 1950) Coincidental plasma-cholesterol and serum calcium levels were estimated most frequently in case 4, and there was a striking parallelism between them (fig 4) Altogether twenty-two coincidental serum calcium and plasma-cholesterol levels were estimated in cases 2, 3, 4, and 6 The coefficient of correlation between these was +0 58, with a standard error of 0 22 There was thus a statistically significant positive correlation between serum calcium and plasma cholesterol levels

In view of this we examined the same relationship in previously published cases in which coincidentally estimated levels are available Lowe et al (1954) reported fifteen such pairs of levels in 7 cases, Dawson et al (1954) five such pairs of levels in 1 patient, and Macdonald and Stapleton (1955) nine such pairs in 2 cases By combining these twenty-nine pairs with our twenty two pairs the scatter diagram shown in fig 6 was obtained The coefficient of correlation of these results is +0 72, with a standard error of 0 14, again indicating a significant positive correlation between serum calcium and plasma cholesterol levels

Certain cholesterol derivatives will in the standard laboratory test for total cholesterol be estimated as the latter substance At the same time it is recognised that some cholesterol derivatives have a vitamin D like effect —e g, vitamin D_3 is derived from 7 dehydrocholesterol Also the healthy infant synthesises cholesterol (Gamble and Blackfan 1920) In view of the hypercholesterolæmia and hypercalcæmia and the demonstrated correlation between them it seems that the disordered metabolism of calcium in idiopathic hypercalcæmia could be related to a disorder of cholesterol metabolism It is tempting to speculate that the latter takes the form of excess production of cholesterol derivatives with a vitamin D-like effect but with other and toxic effects also It is recognised that sterols exist which are antirachitic (and can presumably therefore produce hypercalcæmia) but also predominantly toxic—e g, toxisterol The presence

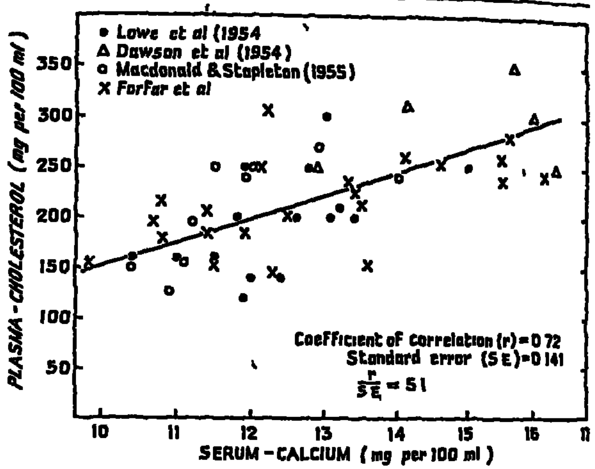

Fig 6—Correlation between plasma cholesterol and serum calcium in present and in previously published cases

of a substance of this kind would be in keeping with the symptomatology and biochemistry of idiopathic hypercalcæmia

The free cholesterol/cholesterol ester ratio was estimated seven times in the acute and early recovery phases of hypercalcæmia (cases 3, 4, and 6) and found to be 0 71–2 17 (mean 1 25) This compared with 0 35–1 03 (mean 0 56) in 10 controls of the same age The rise in the ratio was accounted for predominantly by a rise in the free cholesterol fraction

On serum electrophoresis (case 6) 11% of cholesterol was found to be attached to α lipoprotein and 89% to β-lipoprotein, compared with the usual ratio of a third to α lipoprotein and two thirds to β lipoprotein

No abnormal sterols could be demonstrated by reverse phase chromatography

Effect of Cortisone

Anderson et al (1954) have shown that cortisone reduces the serum calcium level in the hypercalcæmia which may accompany sarcoidosis, and have suggested that cortisone antagonises vitamin D

Cortisone (25 mg daily) was given to case 4 for three periods of five to seven days, and prednisolone (5 mg daily) to case 6 for three weeks On each occasion the serum calcium level fell The balances studied in case 6 showed that prednisolone reduced the retention of calcium and phosphorus (table IV) Cortisone also antagonised the effect of calciferol (table IV)

We conclude from these findings that cortisone reduced the absorption of calcium and phosphorus from the alimentary tract, and that it did so in virtue of an anti vitamin D-like effect

During prednisolone therapy a serum citrate level which had been 0 7 mg per 100 ml rose to 1 2 mg per 100 ml

Cortisone in case 4 did not produce any detectable clinical improvement In fact on three occasions its administration was accompanied by a considerable increase in vomiting It did not cause any consistent increase in weight and did not appear to improve appetite or to reduce lassitude Prednisolone in case 6 appeared to produce clinical improvement Appetite improved, vomiting diminished, and there was a steady gain in weight, which continued after prednisolone was withdrawn Further experience will be necessary before the therapeutic role of these drugs can be adequately assessed

Discussion

Fatal vitamin-D poisoning has been reported in infancy

Malmberg's (1929) patient, who had been given up to 2 teaspoonfuls of cod liver oil daily from the age of 3 weeks,

Preliminary Communication

DETERMINATION OF FŒTAL BLOOD-GROUP

By examining the desquamated cells in the amniotic fluid for the specific sex chromatin discovered by Barr and his associates,[1] it has become possible to diagnose the sex of a fœtus. This method has been described by two of us,[2] and independent development of the method simultaneously in various parts of the world has amply confirmed its reliability.[3–6] We have since tried to develop a method for determining the fœtal blood-group, and we report here the preliminary results of antenatal ABO grouping in the last months of pregnancy from desquamated cells in the amniotic fluid.

If the fœtal blood group can be determined as early as the sex—i.e., from the fourth month of pregnancy—and amniotic fluid can be withdrawn at this stage without disturbing the pregnancy (which we believe but have not yet proved), then it will be possible to diagnose both sex-linked and blood group-linked hereditary diseases at a stage when pregnancy can be safely interrupted.[7]

No simple and reliable method for determining the blood-group from tissue cells was available until Coombs and his co-workers recently described a method by which A and B antigens could be demonstrated on human epidermal cells by mixed agglutination.[8] Coombs et al. believed that this method could be applied to most tissue cells and thus afford a useful tool in studies of the antigenic structure of tissue cells. In our hands, this method has made it possible to detect A and B antigens in the cells of amniotic fluid, all of which are of fœtal origin.

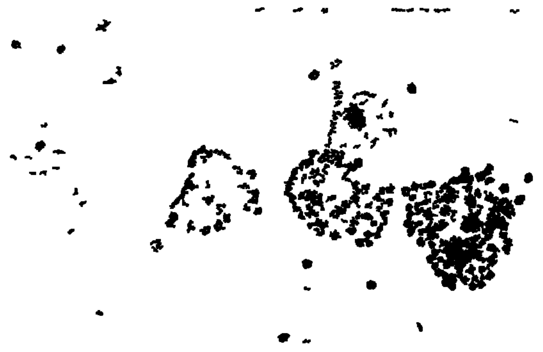

Fig 1—Mixed agglutination of erythrocytes and amniotic fluid cells. Cells do not all participate in agglutination.

Amniotic fluid was obtained by inserting a catheter into the amniotic cavity from below in cases where labour was to be induced, and by transabdominal puncture in a case of hydramnios. 2–5 ml. of each sample was centrifuged for three minutes at 1500 r.p.m. in silicone-coated conical glass tubes. The vernix and the supernatant were removed and the cellular sediment was resuspended in Ringer's solution and centrifuged again. This procedure was repeated once or twice. 10 drops of a suitable cell suspension was then incubated for one hour at 20°C with a similar quantity of anti-A immune serum, and another aliquot with anti-B serum. After this the samples were centrifuged again for three minutes, and the sediments were washed twice with Ringer's solution. Erythrocytes of groups A, B, and O were washed twice, and 1% suspensions with Ringer's solution were made. 4 drops of the cell suspensions was then mixed with similar amounts of the erythrocyte suspensions in silicone-treated test tubes in the following way:

(1) Amniotic cells incubated with anti-A + A erythrocytes.
(2) Amniotic cells incubated with anti-B + B erythrocytes.
(3) Amniotic cells incubated with anti-A + O erythrocytes.
(4) Amniotic cells incubated with anti-B + O erythrocytes.

The tubes were centrifuged and the sediments were then carefully resuspended in the supernatant by gently shaking the tubes. A drop of each cell-erythrocyte mixture was inspected on a slide under cover with an ordinary light microscope or a phase-contrast microscope.

Where agglutination occurred, appearances very similar to those described by Coombs et al.[8] were seen (figs. 1 and 2). The erythrocytes adhered in large numbers to the surface of the much larger amniotic fluid cells, but no agglutination of erythrocytes or of cells alone was seen. When agglutination occurred in mixture no. 1, a fœtal blood-group of A was diagnosed; agglutination in mixture no. 2 was diagnosed as group B; agglutination in both as group AB; and no agglutination as group O. No agglutination occurred in mixtures nos. 3 and 4 in any instance, thus providing a control.

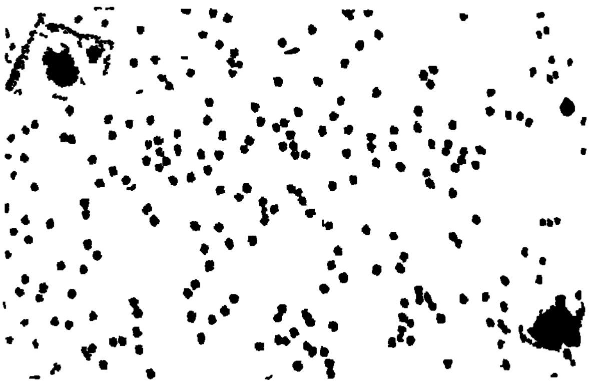

Fig 2—Cell-erythrocyte mixture showing no agglutination.

So far we have studied twelve samples of amniotic fluid, six of which were examined by two of us independently of each other. One sample was found at the first centrifugation to contain blood; contamination with maternal blood was assumed, and this was confirmed by the subsequent examination. In one case very weak agglutination was obtained in mixture no. 1 by both investigators. Postnatal blood grouping of umbilical-cord blood indicated group A. In all the remaining cases except one the results agreed with the blood-groups determined postnatally on cord blood. Only in one case did one of the examiners fail to obtain agglutination in mixture no. 2, where the blood group later turned out to be B. In two instances one of us saw slight erythrocyte agglutination in cases of group O, but no mixed cell-erythrocyte agglutination, which alone is taken as a positive test.

Although the number of samples is small there is no doubt that the fœtal ABO blood group can be diagnosed by this method. How early in pregnancy it can be done is not known, nor has any attempt been made to determine the Rh group as yet. A knowledge of the fœtal Rh-group would be of practical value in cases of Rh immunisation. At present we induce labour in such cases about two weeks before term if the fœtus is estimated at 2800 g. or more; but even in cases where the mother has a high titre of antibodies the fœtus may be Rh negative, and antenatal diagnosis of the Rh group would make it possible to avoid induction of labour in such cases.

died at the age of 4 months with generalised œdema, rickets, and cardiac degeneration

Putschar (1929) described an infant who had been ill from birth and died at the age of 5 months after having had a moderate excess of vitamin D for ninety days

The dosage of vitamin D is given in only one of Thatcher's (1931, 1936) cases About 1500 units daily was given after the first signs of disease had appeared

At necropsy both of Thatcher's cases and Putschar's case had renal calcification in and around the tubules—a lesion now recognised to occur in idiopathic renal acidosis with nephrocalcinosis None of these patients was subjected to biochemical studies They appeared to have been ill before any increase of vitamin D was given, and it is difficult to accept them as proved cases of vitamin-D poisoning or of idiosyncrasy

A more convincing case has been reported by Ross and Williams (1939) in an infant who had been premature at birth and had received vitamin D 20,000–40,000 units daily for several months He died of pneumonia and at necropsy had widespread visceral calcification

Non fatal cases of vitamin D poisoning have been reported by Ross and Williams (1939), Jelke (1946), and Fanconi and de Chastonay (1950) The dosage was 20,000–100,000 units a day for weeks or months

Thus indisputable vitamin-D poisoning in infancy has been associated with very high intake of vitamin D, and even with dosages of this order recovery, if it occurred, took place within a month to six weeks of withdrawal of vitamin D, a considerably shorter period than is required for recovery in many cases of idiopathic hypercalcæmia

It is clear that many of the features of idiopathic hypercalcæmia are in keeping with an excessive vitamin-D effect, but there are also features significantly out of keeping with the known effects of calciferol These two groups are contrasted in table v The hypothesis of hypersensitivity to vitamin D will not accommodate some of the features of hypercalcæmia, unless it is also postulated that the hypersensitivity is accompanied by a profound disturbance of response to vitamin D

TABLE V—FEATURES OF IDIOPATHIC HYPERCALCÆMIA

Evidence of vitamin D like effect	Unlike calciferol effect
Symptoms Radiological changes in bones Increased absorption of calcium from alimentary tract Increased retention of calcium Hypercalcæmia Hypercalcuria Azotæmia Serum alkaline phosphatase level lowered	Vitamin D intake may be low Absence of significant clinical change on administration of calciferol Absence of renal response to calciferol Possible duration of illness after withdrawal of vitamin D Increased retention of phosphorus Hypophosphaturia Hypocitræmia and hypocituria

The postulation that idiopathic hypercalcæmia of infancy results from a disturbance of cholesterol metabolism with the production of a hypercalcæmic but toxic substance could explain most of the features The low intake of vitamin D and prolonged course in certain cases would be understandable The administration of vitamin D might add insult to injury already present but would be unlikely to produce any severe hypersensitivity reaction The lowering of the serum calcium level by a low-calcium diet or by cortisone would, in so far as hypercalcæmia is itself harmful, be beneficial It would not necessarily obviate other toxic effects As a corollary we observed some dissociation between the serum-calcium level and the patient's clinical state symptoms were not worst when the serum-calcium level was highest, nor were they least when the serum-calcium level was lowest If case 5 is accepted as one of idiopathic hypercalcæmia sine hypercalcæmia, his illness cannot have been related only to his serum calcium level, but the conception of a substance predominantly toxic and only moderately hypercalcæmic would explain such a case It would need to be accepted that the mode of action of such a substance differs a little from that of vitamin D—e g, in certain aspects of phosphorus and citrate metabolism

The arithmetical product of the serum calcium and plasma cholesterol levels may have some diagnostic significance In ten estimations on infants aged 6–15 months who were convalescent from, or in the active stage of, other diseases the range of this product was 1007–2726 (mean 1717) In case 5 (serum calcium 11 2 mg per 100 ml) this product was 2946 When he had recovered, the product had returned to within normal limits (1940) So, too, on recovery did the products in cases 2, 3, and 4 become normal (1786, 2047, and 2333 respectively) The term idiopathic hypercholesterocalcæmia would perhaps more accurately describe this disease and would embrace those cases which appear to be of the same disease but by definition are excluded by the term idiopathic hypercalcæmia

There are certain analogous features between idiopathic infantile hypercalcæmia and the hypercalcæmia which may accompany interstitial plasma cell pneumonia, and Hallman et al (1954) suggest that there may be some relationship between the two None of our patients exhibited the clinical features of interstitial plasma cell pneumonia, but 3 of them had had fairly prolonged preceding respiratory infections, which in 1 case lasted three months The clinical course and usually self-limiting nature of idiopathic hypercalcæmia of infancy would be in keeping with an infective ætiology

Summary

5 cases of idiopathic hypercalcæmia are described, together with a possible 6th

In 3 cases the intake of vitamin D was somewhat below that normally accepted in this country, and in only 1 was it above 2000 units a day

Balance studies showed that there was increased retention of calcium and phosphorus

Calciferol produced no significant clinical change and did not increase the retention of calcium more than might be expected in a healthy infant

Moderate hypercalcuria was present, but calciferol did not further increase the urinary output of calcium

The urinary excretion of phosphorus was low

The plasma cholesterol level was usually raised in the active phase of hypercalcæmia This was due to a rise in the free cholesterol fraction There was a significant positive correlation between the plasma cholesterol level and the serum calcium level

The serum citrate level and the urinary output of citrate were those of hypovitaminosis D rather than of hypervitaminosis D

These results are interpreted as showing that, although there is evidence of a vitamin-D like effect in idiopathic hypercalcæmia, neither excessive ingestion of vitamin D nor specific hypersensitivity to vitamin D explains all the features

We suggest that in idiopathic hypercalcæmia a disturbance of cholesterol metabolism produces a cholesterol derivative with hypercalcæmic and toxic effects

The possibility that this disturbance of cholesterol metabolism is due to infection is considered

A low calcium diet induced a negative calcium balance and a lowered serum calcium level without producing any consistent clinical improvement

Prednisolone reduced the absorption of calcium and phosphorus from the alimentary tract

Cortisone lowered the serum-calcium level and antagonised the effect of ingested calciferol

We wish to thank Prof R W B Ellis for his support

Reviews of Books

Peopling the British Commonwealth

G F McCLEARY, M A, M D Camb London Faber & Faber 1953 Pp 174 18s

INTEREST in demography tends to be limited to specialists But the facts it reveals are the concern of us all, as Dr McCleary proves in his balanced survey of the population problems of Britain and the Commonwealth Vital statistics are often dull reading, but he tells his story with skill and a wealth of interesting historical detail By collecting in readable form facts and opinions which are difficult of access to the general reader he has made a useful contribution to the understanding of problems which are being increasingly forced on public attention

Dr McCleary has deliberately confined his book to countries with immigration potential After sketching the historical and political background, he follows the tangled threads of the birth and death rates, and of immigration and emigration since the end of the last century, first in Britain, then in each of the four Dominions In 1883 Seeley predicted that within fifty years the white population of these countries would exceed 100 million In fact seventy years later, it is still only 79 million, and, relative to resources, the distribution is unbalanced Tracing causes and consequences, Dr McCleary shows how voluntary birth prevention has limited the development which was so confidently forecast Can the Commonwealth survive as a viable unit unless the birth-rate rises above replacement-level ? What can be done to redistribute the overcrowded population of Britain to the underpopulated and underdeveloped Dominions ? To these questions Dr McCleary propounds no dogmatic answers He surveys the alternatives and leaves conclusions to the reader, indicating only his preference for planned mass emigration and his realisation that our collective future may depend on switching the contemporary preference for material pleasures to the less immediate but more lasting happiness of a fuller family life

An Outline of the Cytology and Pathology of the Reticular Tissue

A H E MARSHALL, Freedom research fellow, Bernhard Baron Institute of Pathology, London Hospital With a chapter on the Lipidoses by J B CAVANAGH. Edinburgh Oliver & Boyd 1956 Pp 274 116 illustrations 42s

Dr Marshall combines a factual account of our knowledge of the reticular system with a critical appraisal of the many hypotheses which veil the important gaps waiting to be filled in He is not afraid to express his own views, which are based on the records of the London Hospital and the Oxford Lymph Node Registry and supported by his own experimental work At the same time he is commendably cautious in his comparison of human reticuloses and experimental reticuloses in animals

He pays much attention to the often overlooked work of Hortega and de Asua (1921 and 1924) on the presence of microglia like cells in organs other than the brain This is the essential starting point of his work, for he has demonstrated, mainly by the Weil-Davenport technique, the presence of "metalophil" cells throughout the reticular system and in such unexpected places as the advancing edge of the histological tubercle

In reviewing the various clinical and histological types of reticuloses and reticulosarcoma, he largely follows Robb Smith he seems to favour classification by further analysis rather than synthesis His account of 30 cases of lymphohistiocytic medullar reticulosis (Robb Smith 1947), of the Kurloff cell, of Boeck s sarcoidosis, and of mycosis fungoides are particularly helpful of this last disease he insists that the diagnosis should be reserved for cases with a typical clinical course and a predominant skin localisation and should not be applied to examples of generalised reticular tissue neoplasm in which some dermal infiltration has taken place

Dr Cavanagh, of Guy s Hospital, contributes a chapter on the lipid storage diseases which helps to clarify a subject which is becoming increasingly confused

The illustrations of this stimulating book are of a high order

Office Procedures

PAUL WILLIAMSON M D Philadelphia and London W B Saunders 1955 Pp 412 87s 6d

THE title suggests to the British reader that this book is written for the business man in fact, it is full of useful medical information The American doctor's "office" is equipped on a more ambitious scale than is usual in this country, and the procedures which are carried out there include many customarily delegated here to the minor-operation theatre or hospital ward sideroom

Each section contains clear accounts of all the manipulations, manœuvres diagnostic tests, and procedures likely to crop up in general practice The section on pædiatrics, for example, deals, among other things, with treatment of birth fractures and injuries venepuncture, lumbar puncture, examination techniques, numerous sideroom tests, management of herniæ, hydroceles, immunisation and vaccination techniques and circumcision The other sections are built up in the same way, and those on minor surgery, proctology, gynæcology, and the musculoskeletal system are particularly comprehensive

Clear line drawings help the text, and those in the section on minor surgery are especially good They show that, though his equipment would be considered generous in this country the author can improvise shrewdly, finding many uses for an item of equipment found in any office"—the straightened paper clip

Dr Williamson has enjoyed writing his book He writes easily and well, wisely and wittily His book will find eager readers in every casualty department, and among those in group practice It will appeal also to single-handed general practitioners who have a theatre and some occasional help to turn to

The British Pædiatric Association, 1928–1952

H C CAMERON, F.R C P London British Pædiatric Association. 1955 Pp 107

THIS is the story of the first twenty-five years of the British Pædiatric Association The association is as fortunate in its choice of a historian as it has been in so many of its activities Dr Cameron, the biographer of Lord Lister and Sir Joseph Banks and the historian of Guy's Hospital, has written this account of the pædiatricians with delightful grace The birth of the association is portrayed in the frontispiece drawing by Mrs Donald Paterson, in which her dynamic husband, with James Spence in the wings, is persuading a doubtful Dr Still to give the project his authoritative blessing

The newborn association began as a friendly clinical club and has continued, in the atmosphere of Windermere, to maintain this spirit while developing its medicopolitical responsibilities Dr Cameron's story makes it plain that this remarkable fusion of objectives was achieved by the devotion of the men who directed the association s development, such as Frederic Still, Leonard Parsons, and James Spence, their work now completed and Robert Hutchison, Charles McNeil, Cameron himself, and Donald Paterson, still exerting a friendly influence

The book concludes with obituaries in which the author (unlike that famous Guy's man, Samuel Wilkes, whose *vale* to departed colleagues was said to "add a new terror to death"), by his appreciation of the good in the men he describes, makes it appear an "easy and pleasant thing to die." This history happily records the work of a generation who created, we may hope, an enduring tradition for pædiatrics

International Review of Cytology

Vol IV Editors G H BOURNE and J F DANIELLI London Academic Books Pp 396 $9

THE editors have again ranged widely in their choice of topics—from micromanipulative technique to electrochemistry

M J Kopak describes the triumphs of instrumentation by which he is able to investigate the enzymatic activity contained in one millionth of a c.mm of cytoplasm, so much has been achieved in this direction that when the writer states that "it is theoretically possible to identify a single

THE AYLESBURY HOSPITALS, BUCKS

"Damage to one recurrent nerve produces a permanent huskiness of the voice " These words from a well-known textbook on surgical anatomy represent a widely held opinion on the results of damage to the recurrent laryngeal nerves during thyroidectomy

It has always been our practice for an ear, nose, and throat surgeon to examine both preoperatively and postoperatively the larynx of patients undergoing thyroidectomy and, where there is evidence of damage to a nerve, to follow these patients and to assess the degree of disability In doing this, it has become clear that the problem could not be stated so simply as in the quotation given above, nor is the picture so gloomy We therefore decided to investigate the frequency of damage, any predisposing factors that increase the risk of damage, and the subsequent condition of such patients

We examined the records of 300 patients operated on between January, 1949, and December, 1954, for non malignant conditions of the thyroid gland All the cases showing nerve damage were followed up for at least a year , the last case in the series occurred in October, 1954

Operative Technique

The technique of thyroidectomy has remained unchanged for years, being based on that of Joll (1932)

The gland is exposed by a collar incision with separation of the infrahyoid muscles in the midline These muscles are rarely divided, and in no case in this series was it considered necessary to do so In no case was the sternum split to deliver an intrathoracic goitre The inferior thyroid artery is ligated in continuity in the areolar tissue lateral to the capsule of the gland and as close to the carotid sheath as possible, but in a few cases it was not found in this position, and a prolonged search was not pursued The recurrent nerves are not looked for and identified, reliance being placed on leaving a slice of the posteromedial surface of either lobe to protect the nerve To trace the course of the nerves in the neck is only possible after dislocation of the lateral lobes, especially when they are enlarged, and there is little doubt that many injuries to the nerves occur during the dislocation The cut surface of the gland is stitched to the fascia covering the trachea to control bleeding, and only the superficial layer of the wound is drained We always aim at accurate hæmostasis in the area deep to the "strap" muscles, however tedious and time consuming it may be The extent of the resection, of course varies with the condition of the gland, but when the gland is toxic about seven eighths of each lobe is removed

The larynx is examined four days before operation and five days after operation , and, if there is any doubt about whether the nerve is injured or not, the larynx is examined again a month later

Frequency of Damage

In 40 cases there was evidence of damage to one or both of the recurrent laryngeal nerves—a frequency of 13 3% In 22 cases the right nerve was damaged, in 17 cases the left nerve, and in 1 case both nerves were damaged Of these patients 18 recovered completely and 22 did not The bilateral case did not recover In 1 case one nerve had been permanently damaged at a previous operation and the other nerve was damaged in this series There was again no recovery, and a bilateral paralysis resulted

Recovery of Full Movement of Cord

Of the 18 cases (6%) in which full movement of the cord was recovered, 6 had initially a partial lesion of the cord, manifesting itself as sluggishness of the cord and weakness in adduction of the cord, and all these cases recovered rapidly and completely, 5 before leaving hospital and the other 1 within a month Only 2 of these patients noticed any change in their voices

In 11 cases there was initially complete paralysis of a cord in the paramedian position midway between adduction and abduction, and in 1 case the paralysis was partial within six days of operation and complete a month later All these patients recovered full movements within a year The most rapid recovery was in two months, and the slowest in almost a year With recovery in movements went recovery of a full range of voice except in 4 cases 1 patient was still slightly husky, and the other 3 stated that under an emotional strain (usually anger) their voices tended to "fade away," which seemed to indicate early fatigue in the affected muscles

In 4 of these cases difficulties were met with at operation and noted, but in the other 14 cases the operation was uneventful The difficulties were as follows

(1) A large gland displacing the trachea to the left and retrosternal on the right side—the right nerve was damaged

enzyme molecule " the reader is inclined to accept the practicability of doing so as well The second essentially technical paper is by M Wolman and is a useful critical discussion of the mode of action of fixatives and their effects on tissues as subsequently visualised Two interesting communications deal with bacterial morphology, in the first A Marshak discusses the bacterial analogues of the cellular inclusions of higher organisms, and in the other R Vendrely discusses from a histochemical point of view the staining characteristics of bacteria, and includes a consideration of the basis of Gram staining

The papers by D P Hackett on plant mitochondria, and by K Muhlethaler on the structure of chloroplasts are most timely in relation to recent biochemical work on the pathways of photosynthesis N B Kurnick's review of the histochemistry of nucleic acids is notable for a good discussion of the pitfalls of photometric measurements on histological preparations, while R Couteaux's chapter on the localisation of cholinesterases contains some splendidly reproduced photographs and drawings—although the element of subjectivity in drawings is, as always, difficult to evaluate

The contribution by L E Wagge on amœbocytes concentrates on those of molluscs and is in the descriptive tradition, similarly that of H Moe on goblet cells is also broadly descriptive histology, but it includes some quantitative data on the distribution of such cells in the intestine of the cat, though the significance of these data is not altogether clear The remaining papers comprise an informative but inconclusive account of the structure and chemistry of nucleoli by W S Vincent and a short note by E J Conway which summarises recent studies on the redox pump theory of ion transport

This work is not, of course, addressed primarily to a medical public, but the histochemical sections of the book are likely to be very valuable to pathologists who are not specialists in this branch of histology, while many of the other sections will appeal to bacteriologists and biochemists

Tropical Medicine for Nurses

A R D ADAMS and B G MAEGRAITH, School of Tropical Medicine, Liverpool Oxford Blackwell Scientific Publications 1955 Pp 314 30*s*

THE nursing profession now has a more substantial volume on tropical medicine than hitherto For many years the staff of the Liverpool School have taught this subject to general-trained and registered hospital nurses before they went overseas, and it is for them that this book has been written It is definitely not a book on nursing, but it gives an idea of what they may have to contend with in isolated stations in the tropics The subjects are arranged in alphabetical order and each disease is dealt with simply but adequately The 32 figures are very clear and well produced, and the book is admirably suited to its purpose

Bibliotheca Walleriana

A Catalogue of the Erik Waller Collection Vols I and II Compiled by HANS SALLANDER Stockholm Almqvist & Wiksell 1955 Pp 1000 Sw Kr 200

THE Royal University Library of Uppsala was greatly enriched in 1950 when the Swedish surgeon, Erik Waller, presented his library It contains almost all the major medical works published before 1800, as well as a highly representative selection of later literature The famous collections of Osler and Cushing each comprised some 8000 items, but Waller's includes nearly 21,000, and is also superior in quality

The main part of the library consists of old medical literature, including numerous rare and unique books These, together with the 150 incunabula form the first volume of the catalogue The second volume deals mainly with literature of the natural sciences, the history of medicine and science biography, bibliography, and various other subjects, including the collected works of famous scholars and scientists The items are listed under full titles Unfortunately there are no annotations but they would have been an immense job and would have greatly increased the cost

These volumes will be useful to medical and scientific libraries as a check list for exact titles and editions In these days of photo-copying, a catalogue of this kind often reveals the location of a rare book The production of the two volumes is excellent

---

La Lèpre (2nd ed Paris Expansion Scientifique Française 1955 Pp 310 Fr 3800)—In this book Dr Roland Chaussinand, of the Pasteur Institute, has drawn from his own considerable experience in Indo China and has added much of value from the work of others He has substantially enlarged the 1950 edition, and he gives a sound and h description of the disease, its history, epidemiology, bacteriology, immunology, prophylaxis, and treatment There are 130 excellent photographs, of which 18 are coloured and a comprehensive bibliography He condemns compulsory segregation, calling it " illogical, ineffective and dangerous and he emphasises the importance in prophylaxis of case finding and early treatment He also develops his view that tuberculosis and leprosy, by virtue of the relative cross immunity they produce, are mutually antagonistic diseases and he brings the reader up to date on B C G in the prevention of leprosy In his chapter on treatment he clearly states his preference for D D S (diaminodiphenyl sulphone), and deals comprehensively with other aspects such as physiotherapy and surgery It is a pity that so little space is devoted to the histology of leprosy and to describing reactive states there is only a fleeting reference to erythema nodosum leprosum and Lucio's phenomenon is not mentioned Further, many leprologists will disagree with the view that borderline cases always evolve from major tuberculoid and can therefore be considered benign, particularly since 100% have positive skin smears, 86% are negative to lepromin, and the majority become lepromatous These criticisms apart, this is a concise and informative work

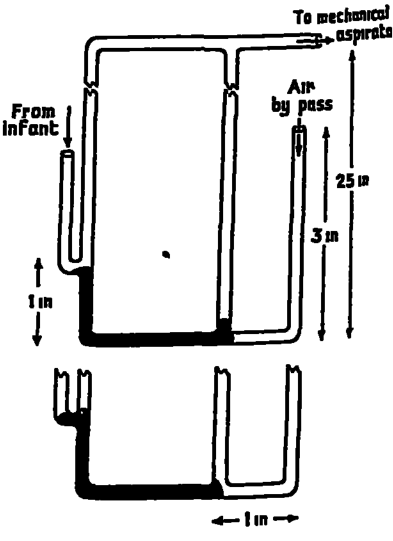
New Inventions

A MUCUS-ASPIRATOR FOR INFANTS

THERE is little doubt that a thorough clearance of the upper respiratory passages is the most important measure in the resuscitation of the newborn This is most commonly achieved by swabbing the mouth and aspirating mucus While this is being done the attendant often sucks and blows through the extractor, which consequently becomes contaminated by micro-organisms Most of the mechanical aspirators designed for suction of the adult respiratory passages are capable of a suction force of 650 mm Hg, which is sufficiently strong to cause serious damage to the pharyngeal mucosa of the newborn



A mucus-aspirator has been designed (see figure) with a "mercury break" introduced between the mechanical force of suction and the infant When the suction force rises above 25 mm Hg, air enters through the by-pass and the pressure returns to atmospheric The oscillation of the column of mercury produces gentle intermittent suction

This mechanical aspirator facilitates early aspiration of the fœtal respiratory passages, especially during cæsarean section and breech delivery, under sterile conditions

Letters to the Editor

CORONARY-ARTERY DISEASE

SIR,—Dr. L Schmidt's comments (Dec 24) are best answered by relating some results of short-term fat-feeding experiments which have been conducted under controlled conditions on volunteers with low serum-cholesterol levels The details of these experiments will be published soon

The basic diet has consisted of maize meal and white bread (estimated fat content 3% of calories) supplemented by sugar and casein in order to maintain by suitable adjustment an isocaloric and isonitrogenous state To this diet various fats and oils have been added in amounts to increase the percentage of calories derived from fat from the basic 3% to approximately 45% and on occasion 70%

Under these conditions, animal fats in the form of beef dripping, butter, eggs, and beef were associated with a prompt and significant elevation of the serum cholesterol level No elevation followed the feeding of equivalent amounts of vegetable oils such as olive oil, sunflower-seed oil, and ground nut oil When ground-nut oil was fed in the hardened or hydrogenated form a prompt rise in the serum cholesterol level occurred One result of the hydrogenation process is the destruction of certain of the highly unsaturated fatty acids, which form only a small percentage of the fatty acid composition of the animal fats used above

By fractional crystallisation we separated out a highly unsaturated and a saturated fatty acid fraction from sunflower seed oil We fed the ethyl esters to a patient whose serum cholesterol level had been raised by a cholesterol (3 0 g) supplement to the basic diet Despite the continued dietary cholesterol supplement, the serum-cholesterol level promptly fell following the feeding of the unsaturated fraction, and an elevation occurred when the saturated fraction was fed later

In Dr Schmidt's criticism of your leading article of Nov 26 on the animal fat theory of coronary heart-disease reference was made to the feeding habits of the Eskimo The animal fat intake of the Eskimo is largely derived from marine animals [1] Marine oils in the form of fish oil, seal oil, and whale oil approach vegetable oils in their fatty acid composition, having a high proportion of the unsaturated fatty acids We have fed seal oil to two volunteers No elevation of the serum cholesterol level followed

In these experiments, then, changes in the serum-cholesterol have been determined by the fatty acid composition of the fats fed, and the consistency of the results has not been affected by alterations in the caloric or protein intake or by switching from maize meal to "baker's cones," a highly refined maize meal from which most of the germ has been removed Nevertheless the views held by Dr Schmidt on maize and bread are somewhat similar to ours, except that we are more interested in the high content of the unsaturated fatty acids in the germ of wheat and maize and not the vitamin E content Burr [2] and Deuel et al [3 4] have shown that the highly unsaturated fatty acids have biological activity in the rat and that the requirement increases as the fat intake increases There is, in addition, a sex difference in the requirements of young rats

Compulsory reversion to the use of naturally occurring vegetable and marine oils, due to the scarcity of animal fat and to bomb damage to hydrogenation plants, could, in our view, explain the striking fall in mortality from circulatory diseases in Norway soon after the German occupation This concept depends on the acceptance of the relationship between the serum-cholesterol level and the incidence of coronary heart disease, but we fully appreciate that more than one mechanism may be operative

RECRUITMENT FOR THE OVERSEA MEDICAL SERVICE

SIR,—May I endorse Mr Seddon's important letter last week ? We all must agree that it is the duty of this country to help those parts of the Commonwealth where the medical services are inadequate

As far as specialist services are concerned, the seconding of registrars can only meet the need to a very limited extent—for two reasons

Firstly a registrar, however skilled, will not have the same prestige as a consultant, not only will this make it harder for him to carry out his work, but the implication that a registrar is good enough is almost certain to provoke resentment in the recipient country In some cases in its early days the World Health Organisation made the mistake of sending personnel of inadequate status, as a medical ambassador only the best is good enough

Secondly, a registrar will inevitably have at least one eye on vacancies at home and will probably think more of the coveted consultant appointment than of his present work

The only satisfactory way to provide adequate specialist service for underdoctored areas is to second consultants —preferably of some years' standing Nor should a period of work abroad be looked on as a loss or sacrifice, I both benefited professionally and made many friends

Finally, important as it is to provide medical aid where it is needed, this aid is as likely to create ill-will as gratitude, especially as the "undeveloped" countries of the Commonwealth become more "developed", at the earliest possible moment a programme of exchanges should be substituted for aid

Robert Jones & Agnes Hunt
Orthopædic Hospital, Oswestry

ROBERT ROAF

BLOOD-TRANSFUSION

SIR,—With much of your leading article of Dec 31 we would agree, but the last paragraph has been too much for us and we must protest against it You quote Dr French as saying that junior residents should not do emergency cross matches, but that the pathologist himself should be called out if necessary You continue, with slight horror in your voice lest Dr French should hear, to reveal the fact that in *some* hospitals technicians are called in for emergency cross matches We declare now for all to hear, including Dr French, that this has been the practice in this and very many other hospitals for some time, and that it is as safe and as satisfactory as any other arrangement, provided the technician is always able to call in a pathologist in any case of difficulty

It has long been known that the greatest dangers in grouping and cross matching are ignorance, haste, and the little slips and errors that human flesh is heir to These dangers are best overcome by good training in the technique and constant day-in and day out experience Technicians have this training, and for the benefit of those who still regard them as "lab boys," able to do the washing up but good for little else, we would point out that the *final* I M L T hæmatology examination is a searching one based on a comprehensive syllabus in which all aspects of transfusion laboratory work are covered in some detail, and in which mistakes are not tolerated Technicians also have the experience, for they do the vast majority of the routine work both in hospitals and in the National Blood Transfusion Service—and you have yourself commented favourably on the accuracy of the

S M S Medical College LIBRARY 1377

blood-grouping work done by the latter No medical qualification can compensate for lack of the necessary technical training or for lack of constant experience in the routine For this reason junior residents are entirely unsuitable for emergency work of this nature, and even pathologists are likely to be less safe than technicians, for there are few, however knowledgeable they may be in transfusion work, who put up routine cross matches Resident clinical pathologists are in this respect better than the clinical residents, but it must be remembered that they are frequently in their first laboratory post and have neither the training nor the experience in serology of a qualified hæmatological technician What are their advantages over qualified technicians who daily undertake this work and who can call on a pathologist in case of need? Is it not nonsense, therefore, to say, as you do, that hospitals without resident clinical pathologists are thereby unfitted to undertake work in which transfusion is often needed?

If, as you suggest, a pathologist is necessary for emergency grouping and cross matching, it follows that he is also necessary during the day-time when it is no less important and no less dangerous As we employ two technicians full time and one part time on grouping and cross matching, it would be necessary for the total medical staff of this laboratory to spend its whole time doing transfusion work And even you, Sir, in spite of your leader, would agree that this would be absurd

We seriously question the wisdom of dividing patients into "dangerous" and "safer" recipients Dangerous recipients there certainly are, but would it not be better to avoid the use of the word "safer" lest it mislead anyone into believing that the cross match is a mere formality? You suggest that when "safer" recipients are to be transfused the emergency can be coped with by "the normal resident staff" with Dr Discombe's book to guide them We presume this means the clinical residents, and we feel that we cannot do better than quote Dr Discombe's good counsel on this subject, on p 14 he states

> "If a clinician is faced with an exsanguinated patient and himself has to decide to administer blood transfusion, to group the patient, and crossmatch a bottle of blood, he must be exceptionally experienced or exceptionally phlegmatic to endure the long wait between starting the test and reading the result Even British phlegm is rarely equal to this task, so that a young clinician hurries over his tests He may easily make an error in the Rhesus group and miss a low titre antibody, or sensitise some young girl to the Rhesus factor and make it unlikely that she will ever have healthy children Every hospital, therefore, must see that the junior clinician on duty need not, whatever the emergency select blood for his own patients"

In conclusion, we would like to say that if a transfusion were to be done on one of us (which God forbid) we would be happiest for the cross match to be done by a technician trained and experienced in hæmatology, knowing that his day-to day familiarity with the technique would guard to a large extent against slips, and knowing that if he was unable to get a perfectly clear cross-match he would call in the other of us, who would decide what was to be done We should be considerably less happy for the cross-match to be done by anyone, pathologist or not, not constantly engaged in this work, however great his theoretical knowledge of blood group serology Technician and pathologist each have their part to play The former carries out prescribed tests and in the vast majority of cases is able to issue blood with an assurance that there is no important incompatibility present In the minority of cases where a clear cross-match cannot be obtained, it is for the pathologist to decide what is to be done next, as here the risks of transfusing and the risk of not transfusing the patient have to be carefully weighed The use of a pathologist for routine cross matches is rather like the use of a steam hammer to crack a nut—not only wasteful of power but also not in the nut's best interests

Pathology Laboratory,
Essex County Hospital
Colchester

JOHN B PENFOLD
J W NICHOLAS

SIR,—May I support your commendation of D George Discombe's booklet[1] In it he expresses t hope that it will be read by housemen It should also b studied by pathologists and technicians, but above a surgeons should read and re-read it, for the commone cause of laboratory error in blood grouping and matchi as Discombe has pointed out,[2] is the worrying clinic who wants blood at short notice

In desperate emergencies group O Rh(D) negati blood (which should be available in every blood bank should be used without direct matching, when th urgency is somewhat less, rapid methods of groupi and direct (cross) matching, taking about half an hou are used It cannot, however, be overemphasised that th quicker the method the greater is the risk to the patient not only of a transfusion reaction but of death Zeitlin[3] states that 1 death results from 2000 transfusions

In your leader you imply that properly matched bloo can be provided within two hours from the arrival of the specimen in the laboratory This is correct only if the patient's group and Rh(D) type is already known and if separated serum is available

If these are not available, using modern approved techniq two hours' incubation is necessary to determine the group an the type of the patient's blood[4] After this has been do two more hours' incubation is necessary for the direct matc (the so called cross match)[5] So, assuming the patient's grou and type are unknown, a minimum of four and a quart hours of laboratory working time is needed (the quarter o an hour being allowed for washing the donor's cells, setti up the tubes, and reading the results) To expect blood to b ready in four and a quarter hours presupposes that a pathologist or technician will be ready to drop whatever he is doi and deal with the request

Many clinicians, remembering the days when bloo was grouped on a tile and matched on a slide in a matte of minutes, but forgetting the not infrequent transfusion disasters, feel that pathologists today are being unreason ably difficult Not infrequently requests for blood fo non urgent cases that are to be operated on arrive so late that there is often less than four hours' working time In such circumstances the pathologist should urge the postponement of the operation unless he is prepared to risk a transfusion reaction or fatal catastrophe To my mind it is unfair that he or the technician should have to take the responsibility for the surgeon's thoughtlessne

Many pathologists would not agree with your paragraph in which you question the reliability of technicians to do grouping and direct matching I am convinced that properly trained and experienced technicians who have had recent practice in the work are entirely reliable A technician or a junior pathologist in doubt or difficulty should always be able to get the help of an experienced pathologist

The technician and the pathologist should be treated fairly by the clinicians, and, as Dr Discombe stresses, they should also be supplied with the essential informa tion about the patient without which the laboratory worker may be seriously handicapped

Pathology Department,
Worthing Hospital

R AIDN

SIR,—In your leading article you quote me (p 1376) as having uncompromisingly said[6] "that junior residents should not be called upon to perform cro matching tests, and that if necessary 'the pathologist must be got out of bed to perform this heavy and responsible task'" The article proceeds "We wonder

Parenteral therapy without a syringe

These new 'Sublings' each contain 10 mg of Testosterone B P in a special water-soluble wax base devised to give perfect sublingual absorption They have been shown to be clinically effective and to produce a 17-ketosteroid excretion rate COMPARABLE TO THAT FROM THE SAME DOSAGE OF INJECTED TESTOSTERONE PROPIONATE

An objective test of the efficacy of treatment is thus available This is in contrast to the almost entirely subjective evidence in therapy with Methyltestosterone B P (whether administered sublingually or swallowed) since this is not excreted as 17-ketosteroids and admittedly gives less satisfaction than injected Testosterone Propionate weight for weight

In Males

Supplementary Therapy

(1) Depression and Debility in middle-aged males where androgen therapy is indicated
1 - 2 Sublings daily

Full Replacement Therapy

(2) As in Eunuchism and Eunuchoidism, etc.
1 Subling thrice daily

In Females

(1) Excessive Functional Uterine Bleeding:
1 - 3 Sublings daily for 3 - 4 days

(2) Inoperable Mammary Carcinoma:
2 - 6 Sublings daily.

Special Articles

BIOLOGICAL EFFECTS OF ATOMIC RADIATION

A REPORT published in Washington last week is the American counterpart of the Medical Research Council's report on Hazards of Nuclear and Allied Radiations, which is the subject of a leading article on p 999 The report is based on a survey by six committees of the National Academy of Sciences The recommendations of the genetics committee include the following

(1) Records should be kept for every individual, showing his total accumulated lifetime exposure to radiation

(2) The medical use of X rays should be reduced as much as is consistent with medical necessity

(3) The average exposure of the population's reproductive cells to radiation above the natural background should be limited to 10 roentgens from conception to age 30

(4) The 10-roentgen limit should be reconsidered periodically with a view to keeping the reproductive cell exposure at the lowest practicable level

(5) Individual persons should not receive a total accumulated dose to the reproductive cells of more than 50 roentgens up to age 30 years, and not more than 50 roentgens additional up to age 40

(6) Techniques for monitoring world-wide fall-out should be further improved

(7) Measurements of the storage of radiation in the stratosphere should be continued and extended

(8) A national agency should control and keep records of all dumping of radioactive material in the ocean

Speaking of contamination by strontium 90 from fall-out after atomic explosions, the report says that already detectable but biologically insignificant traces of strontium 90 have been found in milk supplies thousands of miles from the site of atomic explosions At present contamination of food is negligible "But the maximum tolerable level is not known There is not nearly enough information about the long-term biological effects on man or animals from eating radiation contaminated food Research in this area is urgently needed" The fall-out dose is at present small compared with background radiation and with the average exposure to medical X rays in the United States

CENTRAL HEALTH SERVICES COUNCIL

Symposia

VENEREAL DISEASES AND TREPONEMATOSES

THE First International Symposium on Venereal Diseases and Treponematoses, sponsored jointly by the World Health Organisation and the Public Health Service of the U S Department of Health, Education and Welfare, was held in Washington, D C from May 28 to June 1

Syphilis

Incidence

It was repeatedly emphasised that, although modern methods of syphilis control based on contact tracing and penicillin therapy, can effectively bring down the incidence of early syphilis, some permanent organisation is required to keep it down In the U S A the incidence of early syphilis has declined progressively from 75 6 per *100,000 in 1947 to a provisional figure of 4 1 per 100 000* in 1955 In consequence there has been a considerable relaxation of effort, and case-finding has been less intensive About a year ago the numbers of new cases of primary and secondary syphilis rose in several major American cities Today the significance of this warning is more apparent, and the numbers of cases of early syphilis are increasing in many of the smaller cities with populations of 20,000–200,000 In 1955, of 127 such cities concerning which figures are available, a rise over 1954 occurred in no less than 47 This despite diminished case-finding so the situation is probably even worse than the figures suggest

Serum Tests

With the declining incidence of syphilis some have queried whether the cost of routine serum tests (premarital, prenatal, on hospital patients, &c) is justified by the yield There is no doubt that it is justified, for only by such means can the reservoir of undetected syphilis be disclosed In December, 1954, there was an estimated number of 1 921,000 syphilitics requiring treatment in the U S A Today of all cardiac conditions in adults the only one which is really preventable is cardiovascular syphilis A serum test will reveal latent syphilis before cardiovascular changes have developed, and treatment with penicillin will prevent these from arising

Experience in Russia

From the papers of the three Russian speakers—Prof Boris Mikhailovich Pashkov, Prof Pyotr Vasilievich Kozhevnikov, and Prof Nikolai Sergeivich Smelov—it was evident that in Russia congenital syphilis is not uncommon, and that endemic syphilis exists in some areas There is not yet faith in penicillin as the sole curative agent, and, as was the practice in many European countries until a few years ago, arsphenamine and bismuth preparations are still used in addition

Treatment

Of the purely scientific papers one by A Hurtig (Ottawa), describing the successful combined use of cortisone and antibiotics in a large series of resistant pelvic infections, made a considerable impression In the U S Navy larger doses of penicillin have become necessary through the years in the treatment of gonorrhœa in the Far East Of the newer antibiotics 'PA 105' has been successfully used in the treatment of granuloma inguinale, and spiramycin in the treatment of gonorrhœa and non gonococcal urethritis

Future Action

That the venereal diseases and the treponematoses remain major public health hazards throughout the world, that they are not a hazard of any single nation

INTRAMUSCULAR IRON

Widespread Acceptance...

"The Iron given parenterally was absorbed from the intramuscular site and utilised "[1]

"Utilisation for haemoglobin production was extremely good "[2]

"In every patient a satisfactory rise in the haemoglobin took place "[3]

" all the patients in the series developed a vigorous sense of well-being which contrasted very strikingly with their previous chronic ill-health "[3]

"From the present series it appears that this new iron-dextran complex is a notable advance in the treatment of the iron deficiency of pregnancy "[4]

1 LANCET 1954 2 942.

3 B M J 1954 2 1255
4 LANCET 1954 2 1245

IMFERON IS THE FIRST EFFECTIVE IRON PREPARATION FOR INTRAMUSCULAR INJECTION

IT PROVIDES the rapid, reliable response of an order hitherto only obtainable with intravenous preparations, and it takes much less time to administer

IMFERON is indicated for the patient who is refractory to, or intolerant of, oral iron and when a rapid response is required, as in anaemia of pregnancy

TECHNIQUE

"It was obvious during this study that the skill and care of the person giving the injections does much to minimise local discomfort and staining, and it is significant that only two patients failed to attend for further injections "
(Lancet, 1954, 2, 1245)

and cannot be controlled on a world-wide basis by any nation independently, and that, so long as they exist in any nation, they constitute a menace to all nations, was the collective view of the American Venereal Disease Association, which met during the symposium The association's resolution, which was read to the meeting, urges the maintenance and close integration of a cooperative, international, long-range control programme against the venereal diseases and the treponematoses

An executive committee, of which Dr F W Reynolds (U S A) is chairman and Dr R R Willcox secretary, is to handle arrangements for the International treponematoses award

Medicine and the Law

Incurable Insanity as a Ground for Divorce

Two husbands sued for divorce on the ground that their respective wives had been of incurably unsound mind and continuously under care and treatment for a period of at least 5 years immediately preceding the presentation of their petitions Since 1940 medical evidence has been given at the hearing of insanity petitions by affidavit by the medical superintendent of the hospital where a person alleged to be of unsound mind has been under treatment during the relevant period, and such affidavit, according to a direction of the President of the Probate, Divorce and Admiralty Division,[1] has to state, inter alia, that the patient has been continuously under his care and treatment during the 5 year period and to give his opinion that the patient is of incurably unsound mind In the present cases the treatment of each of the wives had been delegated to consultants on the hospital staffs (under the Ministry of Health ruling of 1950) and the medical superintendents felt themselves unable to swear to all the matters required by the direction of 1940 Additional affidavits dealing with treatment and the incurable nature of the insanity had been sworn in both cases by all the consultants concerned with the treatment of the wives during the 5 year period

The President, Lord MERRIMAN, said that, owing to delegation to consultants of responsibility for the clinical treatment of patients (as distinct from the general care which remained vested in the medical superintendent), the medical superintendent was sometimes unable to give first hand evidence about the diagnosis of the patient's mental illness and the nature of the treatment Accordingly, in addition to the usual matters, the medical superintendent should state that he had delegated responsibility to a consultant, giving the full name of the consultant and the date of delegation In such cases an affidavit would be required from the consultant giving the diagnosis, the nature of the treatment prescribed, any special treatment, and the effect thereof, also, if it were the fact, that in the opinion of the consultant and in the light of the medical knowledge of the day, the patient was of incurably unsound mind and the reasons for that opinion, and whether the patient was able to appreciate extra comforts and if so to what amount If the period of delegation to the last consultant was, on the face of it, insufficient to enable him to depose with certainty, the deponent would be the consultant who had treated the patient for an earlier period of sufficient duration, but, in that case, the evidence would have to be brought up to the date of the presentation of the petition either by the present consultant or the medical superintendent, and the date of the assumption of responsibility by each and any consultant and its duration ought to be specifically stated

His Lordship then granted decrees to each of the two petitioners

Barrister at Law

Parliament

Danger of Children Riding on Farm Tractors

ON the second reading in the House of Lords on June 11 of the Agriculture (Safety, Health and Welfare Provisions) Bill, Earl ST ALDWYN, joint parliamentary secretary to the Ministry of Agriculture, said that every year between five and ten children were killed by falling off tractors There was a real danger here which must be prevented if possible The Bill was read a second time

QUESTION TIME

Fortified White Flour

Last Monday Mr D H AMORY, the Minister of Agriculture, was asked by several members why in face of the evidence of the Medical Research Council and the British Medical Association in favour of National flour he had accepted the Cohen Panel's recommendation in favour of fortified low extraction flour In his replies he said It was because of the conflict of scientific opinion regarding the nutritive value of flour of varying extraction rates that the Government in May of last year invited the President of the Royal Society to nominate a panel of independent persons of accepted authority representative of scientific and medical opinion The whole object of what the Government did was to enable the Government to remain perfectly neutral in this matter as between two strongly expressed medical points of view I should like it to be absolutely clear that we are not proposing to prohibit anybody from eating bread made with flour of any particular extraction rate at all The only prohibition we are imposing is on the use of flour which does not contain a certain minimum quantity of these three token nutrients

Mr F T WILLEY Whilst recognising the right hon gentleman's endeavours to resolve this conflict may I ask him whether he will not admit that he has failed? Has he seen the opinions recently expressed in medical journals, and is he aware that it appears that the weight of medical evidence is against him, in view of this, would he at any rate look at the matter again?—Mr AMORY I think this may well be one of the controversies which will continue until the end of time In the meantime, the consumer will in the future be able to choose the kind of loaf he or she wishes to eat I feel that the Government are not entitled to prevent the consumer from exercising such choice, unless there is incontrovertible evidence that it would be to the detriment of his or her health

Later he added As regards wholemeal bread, of course, everybody will be entirely free to buy it—[An hon member If they can afford it]—and I shall be among them

Dr EDITH SUMMERSKILL While the Minister says that he believes people should have freedom of choice, does he not feel that he has a duty to the poorest in the community, who understand nothing about extraction rates, as we do in this House, and that it is his duty to see that they get, and he helps them to buy, what is best for the nutrition of the family?—Mr AMORY Again, that is precisely why the Government decided to ask this panel of distinguished scientists and medical experts to resolve the conflict of evidence

Expenditure Cuts and the N H S

When Mr HAROLD MACMILLAN, Chancellor of the Exchequer, said he hoped to make a statement shortly about the way in which the Government intends to save £100 million, Mr A W J LEWIS asked Will the Chancellor see that there is no cut in the National Health Service, such as is being rumoured or suggested, particularly in view of the fact that we have had an independent report which stated that the health service should not be cut but that there should be some extension of financial support to it? Is the Chancellor aware that the depreciation in the value of the pound is affecting the health service just as it is affecting everyone? In view of that should there not be increased financial support for the health service?

LONDON SATURDAY, JUNE, 23, 1956

Radiation Hazards

OF the grave questions which faced the Medical Research Council's committee on radiation hazards, two stand out Are X rays as used in medicine today, harmful to the patient or his progeny ? And what are the possible effects both on the race and on the individual of the continued explosion of thermonuclear weapons ? Inevitably the committee had often to base their conclusions on incomplete evidence, and much remains uncertain But by presenting their findings (and their reservations) so plainly, they have made it much easier to see how things stand

The report published last week[1] gives a reasoned and informed assessment of the risks to individuals and to populations Though information on human and mammalian genetic effects is scarce, the committee have tried to place the genetic risks in reasonable perspective In estimating the contribution of the various man-made sources of radiation to the population gonad dose, they have taken as their base-line the natural or background radiation, which has been relatively constant during man s evolution The dose to the gonads from all natural sources has been put at 0 1r per year or about 3 0r per generation of thirty years[2] and in this country man has probably increased this dose by at least 25% in the past fifty years by his use of ionising radiations Genetic damage is irreparable and cumulative, and, since it is the frequency of gene mutation which is increased by radiation the rise in the mutation-rate is directly proportional to the radiation dose received by the gonads Radiation has, of course, no genetic effect after the age of reproduction, but all radiation received by the germ-cells and their ancestors before conception is effective and cumulative The committee find nothing to suggest that radiation-induced mutations will be in any way novel—or beneficial In all probability the mutations to be expected in man as the result of this increased exposure will be qualitatively the same as those already arising spontaneously

The committee were unable to give a figure for the population gonad dose from radiotherapy, it is believed to be considerably less than that from diagnostic radiology, but greater than from any other source Diagnostic radiology contributes to the population as a whole a radiation dose not less than 22% of that from background sources Mr OSBORN and Mr SMITH reported in our columns last week the results of their preliminary survey in England and Wales on which this disturbing figure is based Their survey shows that the annual total of diagnostic X-ray examinations is much higher than had previously been supposed and the American committee which has been examining the situation in the United States have been likewise startled by their own findings (Some extracts from the American report appear on p 1007) On an average, 1 examination is performed every two and a half years on everyone in England and Wales The survey was designed to estimate the minimum contribution of diagnostic radiology to gonad dose in the "genetically alive population"—that part of the population who may become parents This period of risk extends from the conception of the parent to the conception of his or her last child Diagnostic radiology s contribution of not less than 22% of the background dose is several times larger than that from any other source of artificial radiation And this is a minimum estimate Mr OSBORN and Mr SMITH emphasise that the actual dose to the gonads of the "genetically alive" population is greater than their estimate, though whether it is two or five or ten times greater they cannot yet say Whatever the true figure is, it is clearly formidable. Nearly three-quarters of this dose, it seems, comes from a few types of X-ray examination which make up only 7% of the total number of examinations This potentially dangerous group consists in examinations of the hip, femur, lower abdomen, and lumbar spine, and pyelography and pelvimetry The committee recommend that the time has now come for a review of present practice in diagnostic radiology, "both from the point of view of the dose distribution over the population as a whole and from the point of view of the special risks to individuals associated with examinations involving heavy exposure As the report says, a great deal can be done The number of X-ray examinations can be reduced, particularly in young people, and the dose can be cut by more careful radiography, stricter definition of the beam, and the rapid introduction of modern techniques, such as image intensification

Fall-out from test explosions of nuclear weapons adds, at the moment, less than 1% to the background level of radiation, and this source is not, the report says, an appreciable genetic hazard—at the present rate of firing The American report reaches the same conclusion But a very few thermonuclear explosions have made an appreciable addition to the dose, and, if the rate of firing increases, the dose will rise in proportion In dealing with the effects of fall-out on individuals (as opposed to the genetic hazards), the M R C report rightly emphasises that we know very little about the possibilities We have some evidence that patients with ankylosing spondylitis who have had radiotherapy are more liable to leukæmia than those not irradiated But we are particularly ignorant of the consequences of long-continued irradiation by low doses, whether from external sources or from radioactive substances that have been swallowed or inhaled and then incorporated in the body tissues From this point of view, the most sinister constituent of fall out from hydrogen bombs is the radioactive isotope, strontium 90 Since strontium is soluble and behaves rather like calcium, it will be absorbed by mouth and retained in bone Strontium 90's long half-life of twenty-eight years will then ensure a high radiation dose to bone Measurements of the strontium content of human bone have been made in this country to see what the bombs so far exploded have done In an appendix to the M R C. report Dr W G MARLEY records that the maximum activity so far found in Britain was in the skeleton of a one year-old child, which contained 1 2 micromicrocuries per g of calcium Adult bones which have been measured showed lower activities, ranging from

[2] Spiers F W See *Lancet* June 2 1956 p 839

Mr MACMILLAN Of course I shall take carefully into account all that the hon gentleman has said

Medical Aspects of Nuclear Radiation

Replying to a question, the PRIME MINISTER said that the complex matters dealt with by the Medical Research Council Committee on the Medical Aspects of Nuclear Radiation would require careful study by all concerned The findings about radiation from such sources as the diagnostic use of X rays needed much detailed consideration with the appropriate scientific, medical, and industrial bodies To the extent that Government departments were concerned, arrangements were being made for the necessary studies to be made as soon as possible

In reply to Mr WALTER ELLIOT, who asked whether a popular summary of the results could be issued, the PRIME MINISTER said that this would be difficult "Of course, this is not a Government publication, in the sense that it is done by a body entirely free from Government control or influence" But if, after study of the report, the House felt a need for further elucidation, "we will then consider what we can do to help"

Public Health

Poliomyelitis Vaccination

THE first phase of the poliomyelitis vaccination programme due to end by June 30 will now be confined to the 200,000 children in Great Britain who were first selected This is because the safety tests successfully passed by all previous batches cannot be completed on any further batch in time to enable local health authorities to arrange for the inoculation of more children by June 30 In a letter to local health authorities explaining the position, the Ministry of Health has stated that priority will be given to children now registered when vaccination is resumed in the autumn

Antibiotics in Preservation of Fish

Most of the fish eaten in this country is caught between the Faroe Islands and the Arctic Circle and reaches us at the speed of a steam trawler or even slower Even those who sell it will admit that its taste is not that of fish eaten within a few hours of leaving the sea The change is due in some part to the growth of bacteria present on the scales, and the traditional methods of preservation depend on cooling or the action of salt to check bacterial multiplication These were of course devised without any knowledge of bacteriology, and it may well be that the optimum temperature for the growth of the bacteria which cause spoilage is quite low

The Torry Research Station at Aberdeen has recently been making trial of a new method of preservation first suggested in Canada It is found that the addition of 5 p p m chlortetracycline (aureomycin) to the salt in which the fish is packed in the trawler improves considerably the appearance, taste, and smell of the fish on landing The process may add 7–10 days to the "life" of the fish Trawlers would make longer voyages and customers be better satisfied As the law stands, such treatment is illegal; but if the trials are successful there will be strong arguments for adopting this method of preservation It would be foolish to adopt or condemn it in our present state of ignorance

Stewing for 30 minutes destroys the chlortetracycline in fish preserved in chlortetracycline-ice, but frying leaves minute traces There is little information about the effects on man of small and intermittent doses of antibiotics Some animals thrive better and fatten quicker when given a small daily dose of chlortetracycline, but their lives are brutish and short, and long-term effects on them are of no concern It has, however, been suggested recently that pathogenic strains of *Escherichia coli* are liable to appear in herds where the calves receive a diet supplemented by chlortetracycline[1] The Torry Institute is seeking some other antibiotic which will be as effective as a preservative but will be more easily destroyed when its usefulness is over It is to be hoped that the search is successful, for the method as a whole has much to recommend it

In England Now

A Running Commentary by Peripatetic Correspondents

IN medicine, as in the world at large, there is U and non-U

A U doctor is self-revealing in any discussion It is more than being on terms of easy formality with the "right" diseases Your U man knows that the collagen diseases are acceptable nowadays, and could not be caught mentioning such things as "Adaptation Syndrome" or worse still "Stress" But more than that, it is his speech which sets him apart from his non-U fellows—and Fellows "Systemic lupus erythematosus" is U It is non-U to talk of "disseminated lupus," and worse of "D L E" It is non-U to say "periarteritis nodosa", but so very U to talk of "polyarteritis nodosum" In the specialties the schism is more obvious When one hears a neurologist speaking of the "pupillary reactions to light and accommodation" it is certain that he is non-U The U phrase is, of course, "light and convergence" Cardiologists tend in the main to be U, but if they talk of "lifting outflow tracts" you may be sure of it Only the non-U would say "parasternal heave" U rheumatologists speak of "spondylitis ankylopoietica," the non-U ones of "ankylosing spondylitis", and One-up Men call it "Strumpell-Marie disease"

Candidates for consultant appointments may derive some help from the following list though it is incomplete

U	Non U
Endocarditis lenta	Infective endocarditis Subacute bacterial endocarditis
Type 1 nephritis	Acute nephritis
Myelomatosis	Multiple myelomatosis
Addisonian anæmia	Pernicious anæmia P A
Corticotrophin	A C T H
Gall stones	Cholelithiasis
Valvotomy	Valvulotomy
Phthisis	Pulmonary tuberculosis T B
Lymphoma	Reticulosis
Physical medicine	Physiotherapy
Dystrophia myotonica	Myotonia dystrophica
Atrium	Auricle
m eq per litre	Mg %
Hypokalæmia	Hypopotassæmia
E S R	B.S R
Icterus	Jaundice

* * *

To deceive evil spirits (who have very astute hearing) the sickly son in a Chinese household may not be given a name until he has survived the perils of the first year The laws of the Colony previously permitted the addition of the name of the child up to seven years after the registration of the birth, but recently this period of grace has been reduced to one year Full advantage is taken of this privilege by the more conservative Chinese, who have to have time to agree to a name which will be auspicious, will be in harmony with his horoscope, and will not displease his ancestors In the meantime the little fellow may be referred to as "the dog" or even "the buffalo"

It might have been with the idea of fooling the spirits that the Tong-Kang labourer arranged for his wife to be admitted to the tuberculosis hospital under the name of an obliging lady-friend who also supplied the necessary identity card But the subterfuge did not succeed Unfortunately the wife died and the death certificate and burial permit were issued in the name on the identity card Then the trouble started The spirit of the dead wife appeared to the Tong-Kang labourer in a dream and pleaded with him to have these mistakes rectified so that her soul could rest in peace

His first attempt at appeasement was to erect a tombstone with the correct name and a very loving epitaph on it This palliative had no lasting effect In no time the husband suffered painful reminders that the records had not been changed Supernatural dogs scratched his back while he slept Mysterious bruises and swellings appeared on his body Worst of all, the obliging lady-friend (who was legally dead and buried but was in fact hale and hearty although minus an identity card) was threatened with tuberculosis if the necessary corrections were not made in the official records before the moon waned After some confusing Statutory Declarations had sorted the quick from the dead the necessary changes were duly made in the official records

0 05 to 0 2 micromicrocuries per g of calcium It is not surprising that the highest activity was in a child, since growing bone, compared with adult bone, takes up more bone-seeking isotopes Samples of sheep bones contained 14 micromicrocuries per g but in a few mountain pastures figures were up to ten times greater

So far as we know, the M R C committee and the International Commission on Radiological Protection have no records of human damage attributable to strontium In making their recommendations, therefore, they have had to extrapolate from animal work and from the scanty records of human radium poisoning The International Commission recommended that the body burden of radium should not exceed 0 1 microcuries for persons exposed to radiation at work, and it is known that a large safety factor was not included in this figure Easily recognised radiographic bone changes have been recorded in patients with body burdens of from 0 4 microcuries of radium upwards, and radium produced a bone sarcoma in a person with a burden of 3 6 microcuries [3] These effects of radium usually appear after very long latent periods of ten or twenty years Larger body burdens may, of course, be associated with different and earlier changes, as in the American dial painters [4] who had massive bone necroses, infections, and aplastic anæmia (these "aplastic anæmias" might today have been diagnosed as acute aleukæmic leukæmias) Though damage by ingested radium in man has been known for many years, there are as yet no data on the ultimate results of long-continued low-level activity from ingested radium in a "closed population"—i e, one which has been followed up to extinction There is, therefore, no evidence about the possibility of premature ageing or chronic ill health in man as a result of irradiation Such changes have been observed in animals [5] It is hard to say how radium and strontium compare, but the biological effects in bone of alpha-particle emission from radium are probably greater than the beta-radiation from strontium-yttrium decay In view of this difference the International Commission recommended a higher maximum permissible body burden for strontium than for radium —namely, 1 0 microcuries for those occupationally exposed This corresponds to 1000 micromicrocuries of strontium per g of calcium in the skeleton, which is about a thousand times greater than the most heavily contaminated bones yet examined But the M R C committee declare that "immediate consideration would be required if the concentration of radioactive strontium in bone showed signs of rising greatly beyond that corresponding to one hundredth of the maximum permissible occupational level" In other words if it goes above 10 micromicrocuries per g

If, in fact, poisoning reaches that level it is likely to do so first in young people with growing bones It is also reasonable to suppose that, apart from this age difference, the whole population would be equally affected It seems that the fall out of thermonuclear explosions is deposited at the rate of 10–20% per year, so that strontium would continue to find its way into bone for years after the "alarm level" had been reached No doubt this is one of the reasons for the guarded words which the M R C committee uses about the hazards of fall out from test explosions They say that the hazards from external radiation due to fall-out are so far negligible, and no detectable increase in the incidence of ill effects is to be expected from internal radiation by radioactive strontium at its present level But if the rate of firing, particularly of thermonuclear weapons, increases, harm may be done in a small proportion of the population The report makes no estimate of how big an increase in the rate of firing would be required to produce the first detectable, and presumably gross, damage This question of poisoning by strontium 90 is one on which the medical profession, like the M R C committee, can only advise on the possible results of continued exposure It is the committee's view that, with proper safeguards, exposure from all sources in peace time can be maintained at levels which can be accepted by the citizen "without undue concern either for himself or his offspring" But unless the safeguards include the stopping of further thermonuclear tests, is this conclusion justified? By the time we have gathered sufficient evidence to assess more accurately the danger of strontium 90 poisoning, it may be too late to prevent disastrous consequences

Pyelonephritis

PYELONEPHRITIS is the commonest disease of the kidneys [1] In some forms, such as "pyelitis" of children, its course is relatively benign, and acute attacks in the adult can readily be controlled, after identification of the causal organism, by appropriate treatment Recurrent and chronic attacks, however, are very resistant to treatment On p 973 this week, Dr JAN BROD points out that, while chronic pyelonephritis is the commonest cause of deaths from renal failure in Prague, two-thirds of the cases had escaped clinical recognition In an attempt to improve this situation, Dr BROD compared the clinical features of 132 cases of chronic pyelonephritis, 54 of chronic glomerulonephritis, and 16 of vascular nephrosclerosis, and his inquiry throws welcome light on a confused subject The well-known diagnostic points were not always as helpful as expected pathogenic organisms were grown from the urine in 81% of cases of chronic pyelonephritis, but also from 50% of cases of chronic glomerulonephritis On the other hand, a large excess of white blood-cells was found in the urine of 76% of those with pyelonephritis, as opposed to only 14% in glomerulonephritis and vascular nephritis Otherwise, the most helpful and easily determined abnormality was a long-continued loss of renal concentrating power, quite out of proportion to the degree of impairment of the glomerular filtration rate This disorder of the distal tubules included decreased ability to save base (Na), and there was a tendency towards dehydration, decreased alkali reserve, and acidosis Another point of diagnostic importance was a striking difference in the function of the two kidneys in chronic pyelonephritis, as assessed by ureteric catheterisation, using the concentrating index of endogenous creatinine ($\frac{U}{P}$ ratio), the difference was insignificant in normal kidneys and in those affected by chronic glomerulonephritis

So far the soul of the dead wife appears to have found peace The Tong-Kang labourer came to the Health Office yesterday looking a different man He has put on weight, is sleeping well, and no longer fears he is going mad And the obliging lady-friend's cough is quite better

* * *

Correcting an examination paper recently I came on this "Pyelitis Recognised by looking at the urine 1 gross—opalescence 2 microscop—pus cells de luxe" A week later, at the end of the oral examination, I asked the writer what "de luxe" meant For a moment he looked puzzled and then said with relief "Oh, dee lux Well it means plus plus, sir" "In what language?" "Slang" Nonplussed (pas de luxed), I let him go

He was a great linguist, that fellow He described the signs of umbilical sepsis as "calor, dolor, rubor, edema, læsio infunctio" (Omphalological papers please copy) Furthermore, he always wrote et instead of and "Home helps for the aged have been a terrific boon The G P can keep in touch c̄ the other health workers in the district by inviting them to tea every now et then et exchanging ideas et experiences for the mutual benefit of his panel patients"

I wonder why he emphasised tea as the collation Surely on a Sunday morning the health visitors, &c, would enjoy sherry et cake c̄ the dr

* * *

I have just obtained my second child's birth certificate There is nothing remarkable in that thousands of British fathers have shared the experience during the past year All I had to do was to drive into the sleepy afternoon streets of the nearby market town, walk up a flight of stairs, and recite *sotto voce* to the registrar the required particulars There was no-one in the waiting-room, no-one else in the office save the registrar's clerk 3*s* 9*d* changed hands in a somewhat furtive, uncommercial fashion, I was given a couple of N H S forms, and the birth certificate unostentatiously reached my private address the following morning

How different was my experience, two years ago, when my firstborn arrived! I met my two witnesses (one Italian, the other American) outside the vast, imposing Register Office in Rome, at 8 A M Unless one was there at opening time, there wasn't a hope of completing the formalities before the office closed at 2 P M Inside, the milling crowd divided itself roughly into two preliminary queues (easily recognisable by their respective demeanours), one to record births, the other deaths But this, which took perhaps twenty minutes, was only the beginning We next proceeded upstairs to sign the registration book, in the presence of one of a team of registrars, working three to a room and maintaining a steady output of one registration every two minutes or so A weighted handclasp with an attendant speeded our progress at this point, we had not waited more than a quarter of an hour before we were giving the usual particulars to a registrar, who wore the black gown of the Italian civil servant and had the little finger-nail of his right hand carefully tapered to an inch-long point

The birth was now duly registered, and my witnesses could leave, but I had to go through a fresh sequence of formalities in order to obtain the certificate I waited in another queue to apply for the certificate, and in yet another in order to pay the fee The certificate would be ready the following morning, and once more I appeared promptly at 8 A.M, and got the certificate after a relatively short wait Finally I went to the British consulate and registered the birth a second time The whole procedure cost about 1*s* 9*d* for the Italian certificate, 8*s* for the British one, but the Italian document is better value for money being gaily adorned with coloured stamps and impressed with the magic letters S P Q R I have only to look at it to see once more the mimosa blooming in the Roman gardens on that April day

Of course it's all a question of national temperament and I would not presume to say whether the Italian way of doing things is better for being a challenge to one's tenacity, or the English for being so much simpler

Letters to the Editor

USE OF VITAMIN K IN THE NEWBORN

Sir,—The standing committee of the British Pædiatric Association on prematurity, in their letter last week,[1] have done well to emphasise the danger of overdosage of vitamin K This warning comes most opportunely closely following the account by Dr Bound and Dr Telfer (May 19) of the effect of large and small doses of 'Synkavit' on plasma-bilirubin levels in premature infants

This is yet another example of how easily valuable therapy in moderate dosage can become a menace when given in excess of requirements Such lessons are only learned by bitter experience They bring to mind other relatively new diseases, such as retrolental fibroplasia following the over enthusiastic use of oxygen, and "idiopathic" hypercalcæmia, probably the result of carrying prophylaxis against rickets too far in the current manufacture of infant foods in this country[2,3]

The Hospital for Sick Children
Great Ormond Street
London W C 1

BERNARD SCHLESINGER

Sir,—The findings of Dr Bound and Dr Telfer prove beyond all doubt that large doses of vitamin K administered to premature babies increase the hyperbilirubinæmia, thus contributing to the development of kernicterus The mechanism of this action—whether stimulation of hæmolysis or diminished excretion of bile-pigment by the liver—is regarded by the authors as undetermined

May I call attention to a paper published several years ago[4] in which my associates and I showed that in the active phase of epidemic hepatitis the hyperbilirubinæmia appreciably increases in the eight hours after intravenous injection of the same water soluble vitamin-K analogue (synkavit)? The dose of 70 mg we administered to adult patients is rather small, compared with 50 mg for premature infants, but the rise of plasma-bilirubin level amounted on average to 3 2 mg per 100 ml in thirty tests (minimum 1 8 mg, maximum 17 0 mg) This immediate effect, observed only in icteric hepatitis, was absent in obstructive jaundice and Laennec's cirrhosis Hæmolysis being out of the question, it was attributed to a temporary reduction, caused by functional overtaxing, of the liver's capacity to handle bilirubin The same mechanism probably accounts for the more protracted and dangerous action of considerably heavier doses (per lb body-weight) in premature infants

BREAD

Sir,—For anyone to show a reasonable interest in the nutritional value (rather than the preservation) of food often suggests beards and sandals as well, further it is probably not difficult to acquire a reputation as a food faddist even when the approach to the subject is quite objective But the problem of flour extraction rate so fully set out in your editorial of June 9, is not a matter of fads or fancies, it is a matter of fact to which the M R C Conference report gives as clear a basis from the scientific aspect as is yet possible to find Even so no claim is made that the data presented are by any means the last words on the subject, this alone would, one imagines, have caused the panel on flour to have paused before making too definite recommendations

or vascular nephrosclerosis X-ray examination, and especially serial examination, in chronic pyelonephritis, often showed differences in size and density of renal shadows and in spread and evacuation of contrast medium Consideration of these points would undoubtedly help towards more widespread recognition of the condition

The clinical picture has been correlated with the common pathological finding of irregular superficial depressions associated with wedge-shaped scars through the kidney parenchyma [1–6]—a type of lesion sometimes ascribed to ischæmia [7] or developmental dysplasia [8, 9] The possible relation of these scars, and therefore of pyelonephritis and the resulting vascular changes, to a type of hypertension [1, 3, 5, 10] is of the first importance Experimental evidence now provokes further thought on this subject De Navasquez [11, 12] found that when gram-negative bacilli were injected intravenously into animals with normal kidneys, the organisms did not leave the blood-vessels but passed through the organ harmlessly and never appeared in the urine But when coagulase-positive *Staphylococcus aureus* was injected pyelonephritis followed and renal scarring developed with the same features as the human disease localisation of the organisms was presumably due to diffusion of coagulase from the plasma to produce coagulative necrosis in the surrounding tissues, thus enabling the organisms to multiply in a presuppurative phase before the phagocytes could reach them In animals which had survived a staphylococcal infection and had presumed scars (later confirmed), intravenous injection of gram-negative bacilli of the coliform group invariably produced an acute pyelonephritis which was fatal within two weeks The kidneys showed asymmetrical contraction, with coarse stellate scars resulting in an intrarenal hydronephrosis In addition to these old scars, there were linear abscesses in their immediate vicinity, the purulent exudate being confined to the distended tubules, and the pelvis showed patchy inflammation It seemed that the intrarenal hydronephrosis resulting from the first infection had slowed the blood-stream sufficiently for the second infecting organisms to multiply and produce suppurative lesions This was further evidence that, in kidneys without mechanical defects, infarctions or atheroma, these stellate scars were the result of hæmatogenous pyelonephritis De Navasquez pointed out that the primary staphylococcal infection in the rabbit, with appropriate dosage of organisms, was self-limiting and left no clinical evidence, but it enabled the gram-negative bacilli to settle out in the kidney when they would not otherwise have done so But we must not conclude from these animal experiments that in man a previous infection must be staphylococcal before a coliform infection can take hold Moreover, the way in which these animals were infected (20–100 million bacilli were injected into an ear vein) is artificial and gives no clue to the method of infection in man The secondary infection in the rabbit led to death from progressive uræmia and anuria, but, as De Navasquez explained, this is because the rabbit's kidney is monopyramidal, and obstruction at the single papilla by a small lesion can affect all the collecting tubules, whereas the multilobular human kidney has a much greater margin of safety

The development of these scars was also examined by Heptinstall and Gorrill,[13] who injected *Staph aureus* into rabbits, some of which were kept alive with penicillin They then examined the kidneys at intervals up to four months Again, the naked-eye and microscopic appearances were very similar to the scars attributed to pyelonephritis in man Heptinstall and Gorrill then produced a unilateral pyelonephritis with a coliform organism by temporary occlusion of one ureter [14, 15]—a procedure which localised the infection to the affected kidney while the other remained normal After three days the ureter was released and either then or at periods up to four months, the normal kidney was removed In this group of animals, the blood-pressure was measured at least twice weekly It was found that there was no elevation of blood-pressure with a unilateral infection when the opposite kidney was intact and even when it was removed the blood-pressure rose only when there was considerable scarring in the affected kidney In the scarred areas in all kidneys infected for over forty days, arteries and arterioles seemed to have increased in numbers, merely because of the disappearance of tubules The only structural change in the vessels was an increased cellularity of the media in the older infections and nothing significant was found in animals with high blood-pressure It may well be that the design of the experiment did not allow the high pressure to continue long enough for changes to develop Thus, in the animals, a rise in blood-pressure was due, not to vascular changes, but to extensive scarring in a remaining single kidney

Patients with chronic pyelonephritis do not necessarily develop hypertension Of Longcope's [16] patients with chronic pyelonephritis, those without hypertension had normal vessels and some with severe hypertension had vessels with slight changes Weiss and Parker [1] formed a more definite view from their cases of chronic pyelonephritis, mild proliferative vascular changes were associated with normal blood-pressure, and severe changes were almost always associated with severe hypertension On the other hand, Goldring and Chasis [10] found evidence that pyelonephritis did not cause hypertension, for hypertension was not more frequent in their patients with pyelonephritis than in those without From their study of 11 kidneys removed for hypertension and found to show scars of chronic pyelonephritis, Pickering and Heptinstall [5] concluded that the renal lesion was sometimes the cause of the hypertension but the evidence regarding the separate responsibility of the pyelonephritis and the vascular changes was too conflicting for either to be held

A pause would have been desirable if only because bread, itself a staple article of diet and likely to be increasingly used as such, is not the only food which is nowadays tampered with, preserved, or even misrepresented, despite legislation to prevent at least some of these happenings. As a profession we are inclined to take short-term views of cause and effect, and a sentence in the M.R.C. Conference report should be drummed into everybody: "the absence of recognisable illness in an individual is not a sufficient criterion that his diet is nutritionally sound."

I have got myself into trouble in the past because of my objections, for quite clear reasons, to the pasteurising of milk as an end in itself; amongst these objections is that we know from experimental work and simple observation that heat-treated milk loses something more than part of its ascorbic acid content. The usual reply to this is that deficiencies are made up by other articles of food. If one by one the principal articles of food are going to be denatured with official connivance, where shall we finish up? Everybody agrees that all sorts of what are called metabolic or constitutional diseases are on the increase; while it would be stupid to assign their basic pathology necessarily to nutritional causes, at least it makes some of us wonder. There is plenty of evidence from nutrition experiments on laboratory animals that queer things can happen; even clearer is the evidence on a long-term basis from experience in feeding livestock generally in which changes are more readily observed than in man. But the human animal, for better or for worse, is so resistant to abuses of its economy, whether nutritional or other, that lots of things which must be there to be seen are missed because we do not know what to look for. Since food is the most important of the triad governing life—food, warmth, and shelter—it ill behoves us to monkey about with food too much until we are more sure of our ground.

A recent experience emphasises how much remains to be learnt about nutrition of quite a simple kind. For a number of years I have bred and reared cattle, and in a national show just a fortnight ago I won amongst other prizes one for a sixteen-month-old heifer. This rather surprised me as her nutritional state in the ring was not so good as it had been a few weeks before the show when she was brought in from the herd and given, with a companion, special scientific(?) feeding, as is usual preparatory to such an event. On returning from the show she was turned out with others into an old orchard carpeted with rough old herbage and within a fortnight she has found for herself a diet which has filled all the hollows that special attention did little to correct. So much for thinking one knows anything about feeding animals. What about human dietary—so easily influenced by Authority?

London, W.1 W. R. THROWER

TUBAL OCCLUSION

SIR,—Last week Mr Green-Armytage stated that there is danger in the doctrine that "among patients attending infertility clinics who are found to have blocked tubes, spasm, irritability, anæsthesia, nerves, or even frailty in deductions and methods, are the causes of tubal occlusion in all but 6–7% of cases." After reading this, it is instructive to turn to what Professor Polanyi says in the same issue:

> "Science is said to describe *facts* which are there whether you like them or not. . . . The function which I attribute here to scientific passion is that of distinguishing between demonstrable facts which are of scientific interest, and those which are not."

For many years now, I have taught and written that a *minimal* criterion for tubal occlusion should be two negative tubal insufflations at 250 mm. Hg plus a confirmatory hysterosalpingogram, on separate occasions. Even this criterion is not proof-positive of non-patency of the tubes. For too many years a single insufflation finding of non-patency at 200 mm. Hg, or a single hysterosalpingogram which shows apparent non-patency, has been accepted by many gynæcologists as denoting tubal blockage. The importance of tubal spasm, simulating tubal blockage, can be easily demonstrated: every case which shows apparent non-patency at 250 mm. Hg under anæsthesia, should have a repeat insufflation a few days later without anæsthesia, when normal tubal patency and function is seen in two out of every three such cases. This result has been obtained by me in more than 300 such tests and without the preliminary use of amyl nitrite or any antispasmodic.

I am interested in Mr Green-Armytage's statement that tuberculosis alone accounts for 5–6% of all occlusions. In a paper presented before the Royal Society of Medicine in 1943, I propounded the view, for the first time, that tubal blockage may in a considerable proportion of cases, be due to subclinical tuberculous salpingitis.

DIAGNOSIS OF THYROTOXICOSIS

SIR,—I was interested to read last week's letter by Dr Freeman and Dr Mattingly on the diagnosis of doubtful cases of thyrotoxicosis.

The differentiation of thyrotoxicosis from an anxiety state is one of the common problems of general practice, and one which often involves referral to hospital with expensive and time consuming investigations. The measurement of sleeping pulse-rate would be a very simple investigation in general practice if it were possible to use a fairly short-acting hypnotic such as intramuscular paraldehyde; and I would be interested to know whether a true resting pulse rate is obtainable in this way. If so admission to hospital for three days, as suggested by your correspondents, would seem unnecessary and extravagant.

London, W.11. J. TUDOR-HART

A SHORT SMALL INTESTINE ASSOCIATED WITH FIBROSIS OF THE LIVER

SIR,—The article by Dr Raeburn and Dr Brafield (June 9) calls attention to the association of a short small intestine with fibrosis of the liver. This association does not seem to be always present, as the following case shows.

A woman, aged 55, had had intermittent vomiting for the past six months. A barium meal investigation revealed partial obstruction at the duodenojejunal flexure. The proximal 4 inches of the jejunum showed constant narrowing of the lumen with rigidity of the walls and complete loss of the mucosal pattern. The small gut appeared to be short but was otherwise normal. A diagnosis of malignant neoplasm of the jejunum was suggested.

At necropsy (Dr W. I. Leslie) a congenitally short jejunum and ileum, measuring 8 feet together, was found. The proximal part of the jejunum was bound by firm adhesions to the tail of the pancreas; its lumen appeared to be narrowed and somewhat kinked, but its wall was not infiltrated by growth. There was a scirrhous carcinoma in the distal half of the pancreas. The spleen showed nothing abnormal apart from intense congestion. The liver was firm and was not enlarged; on section numerous metastatic tumour nodules were found widely distributed throughout the parenchyma.

In this case of congenitally short small intestine no evidence of fibrosis of the liver was present. Possibly the short jejunum, being in closer contact with the tail of the pancreas than is usual, caused chronic irritation by intermittent pressure, thus contributing to the development of cancer in this region.

London, W.1. A. ELKELES

responsible Dr Brod's findings are that hypertension develops with increasing frequency as the pyelonephritis progresses, to the same degree as in chronic glomerulonephritis, though four times more often than in chronic cholecystitis (taken as a control for other chronic infections), his biopsy studies rebut the idea of a vascular cause, since vascular lesions were absent in 5 patients with grave hypertension Malignant hypertension developed at an earlier age in pyelonephritis with hypertension than in essential hypertension, but only when the renal disease was far advanced His results are in line with the experimental findings in suggesting that the onset of hypertension is determined by the lack of sufficient healthy renal tissue (or the presence of sufficient diseased renal tissue) Whatever the ultimate answer to these unsettled questions may be, all cases of pyelonephritis must be treated seriously and every resource must be used to eradicate the infection as completely as possible at the earliest opportunity

Steroids in Anæsthesia

Some years ago Selye[1 2] demonstrated in rats the anæsthetic properties of 75 steroids with various structures He noted that some compounds were potent anæsthetics but had little hormonal activity Subsequently, hydroxydione (21-hydroxy pregnane 3, 20-dione sodium succinate), a water soluble steroid, was shown experimentally to have a wide margin of safety and to be a likely drug for clinical use[3] Indeed, work on various animals indicated that it has a therapeutic index considerably greater than that of thiopentone[4], hydroxydione has no hormonal activity[5] Under the name of 'Viadril,' it was first described in use as a clinical intravenous anæsthetic last year[6] Although it is not a barbiturate, it lends itself to comparison with thiopentone, and other thiobarbiturates, because of its similar effects and method of administration The early reports suggested that it had some advantages over these drugs both in its ability to produce greater relaxation without correspondingly increased medullary depression and in its seemingly specific action on the reflexes of the respiratory tract But some later findings have been less encouraging, and the disadvantages of the new anæsthetic have become more apparent

On another page this week Dr Galley and Dr Rooms describe their experiences with hydroxydione, and pharmacological and other clinical investigations have lately been reported elsewhere[5 7] From the start, it was realised that hydroxydione was an irritant, and in one series venous thrombosis followed in 15 out of 70 patients who received dilutions as low as 0 5% given as part of a freely running infusion Dr Galley and Dr Rooms find that 2 5 g dissolved in a 540 ml bottle of saline solution gives no trouble These dilutions, however, necessitate the use of large volumes of fluid to get even a small quantity of the drug into the patient—a cumbersome method of inducing anæsthesia More concentrated solutions cause pain (unless injected very slowly) and, commonly thromboses With the dilute solutions, loss of consciousness is slow, very closely resembling the onset of natural sleep but depending on the concentration rate of injection, and state of the patient Drowsiness may take as long as five minutes to appear, and sleep a further five minutes The full anæsthetic effect is often not attained until fifteen or twenty five minutes after the initial injection A slightly quicker result can be achieved by speeding up the rate of injection, but hypotension may result Experimental work on cats[7] suggests that the hypotension is caused by inhibition of the vasoconstrictor centres in the brain, coupled with a direct vasodilator action on the peripheral vessels themselves But hydroxydione also depresses the ventricular muscle, though not so much *nor for so long as an equivalent dose of thiopentone* Dr Galley and Dr Rooms have observed hypotension, even in young patients, and an increased pulse-rate irrespective of a fall in blood pressure *Respiration is seldom greatly influenced, but* the volume may be reduced slightly and the rate increased[7] Apnœa, such as is often caused by thiopentone, is very unusual Investigation of the duration of action suggests *that 1 g* lasts for about two and a half hours[8]

There is little evidence that hydroxydione is an analgesic, and, under apparently deep anæsthesia with hydroxydione alone, sensory stimulation produces immediate reflex activity This response is very similar to the reaction of patients under thiobarbiturates, such as thiopentone, and indeed electroencephalography has failed to show any difference between hydroxydione and these ultra short acting drugs[5 9] These facts are substantially in favour of its classification as a hypnotic rather than as an analgesic On the other hand, all reports have remarked on its selective depression of laryngeal and pharyngeal reflexes, without medullary depression This action is the opposite of what may be expected under barbiturate anæsthesia, when many reflexes in this area are often exaggerated, and it is a big advantage for some operations A further difference seems to be the remarkable sense of well being and lack of fatigue during the first twenty-four hours after operation in patients anæsthetised with hydroxydione

It is too early to assess the value of steroids in anæsthesia Despite the valuable evidence given by Dr Galley and Dr Rooms, many anæsthetists will not yet be convinced that hydroxydione has much to offer that cannot already be achieved with fewer disadvantages by existing drugs Unless the anæsthetist takes the chance of venous thrombosis and hypotension by giving a more concentrated or more rapid injection, induction takes too long for all but major operations Moreover the selective depression of respiratory-tract reflexes, when continued into the postoperative stage, may well increase the ever present dangers of this period Nevertheless the investigation of hydroxydione has opened up possibilities in a new line of anæsthesia which may well culminate in valuable additions to those drugs which have stood the test of time

GIANT HYPERTROPHIC GASTRITIS

SIR,—Giant hypertrophic gastritis is generally considered a benign condition Dr Williams (April 7) suggests that an extensive resection through healthy tissue, as for carcinoma, is unnecessary, and Mr Park (May 19) advocates resection of part of the affected mucosa

Penetration of the muscularis mucosæ by epithelial elements was not mentioned by Menetrier [1] or by Spriggs [2] but has been described as occurring in giant hypertrophic gastritis by a number of subsequent writers including Dr Williams Grime and Whitehead's [3] case is cited as evidence that giant hypertrophic gastritis is a benign condition, since their patient was well 13 months after incomplete removal of the affected stomach, but this stomach showed no submucosal penetration Maimon et al [4] describe submucosal penetration in three of their six cases, stating that "it does not suggest neoplasm, it is equivalent to the type of herniation commonly seen in the secondarily contracted gall bladder producing the gland spaces which are called crypts of Rokitansky"

On the other hand Brunn and Pearl [5] say that the only certain sign of malignancy is the invasion by the epithelium through the muscularis mucosæ, describing cases of the allied and often associated condition of multiple gastric polyposis, they found evidence of carcinoma in 12% and, in a later paper,[6] in 19 out of 37 cases

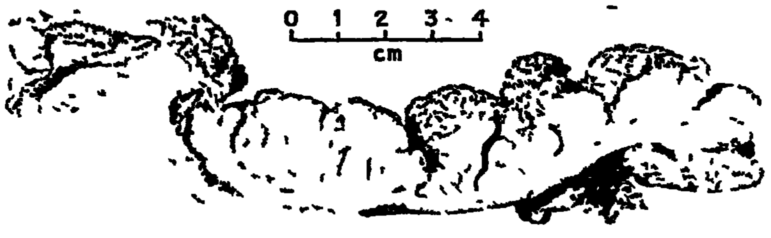

Fig 1—Stomach wall Compare hypertrophied portion with normal on left

Histologists are accustomed to regard invasion of the submucosal stroma by epithelial elements as a major criterion of malignancy in the large intestine The following case raises the question of whether it should not be so regarded in the stomach

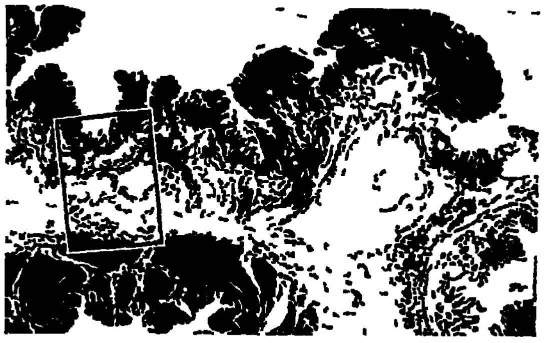

Fig 2—Section of hypertrophied stomach wall (× 5)

A man of 57 years came to hospital with epigastric and left subcostal pain, of 4 months' duration, unrelated to meals, posture, or exercise but relieved by milk Each night he had severe pain lasting 15 minutes, and all day he had an ache He had nausea but had not vomited, and he had been constipated for 7 weeks Hæmoglobin 113% Histamine test meal free acid, mucus, but no blood Barium meal suggestive of gastric carcinoma

At laparotomy, by Mr G O Jolly, the stomach wall was found to be greatly thickened, and was recognised as an example of giant hypertrophic gastritis, but at the cœliac axis there was what appeared to be a carcinomatous lymph node No other site of primary carcinoma could be found, so a total gastrectomy was performed

The mucosa, over an area 16 × 13 cm in the fundus was much hypertrophied and thrown into rugæ 1 5 cm across and 2 5 cm high, resembling cerebral convolutions (fig 1) The mucosa was everywhere freely mobile over the muscle No polypi were present There was no evidence of past or present ulceration

On histological examination the affected mucosa is greatly thickened but maintains the normal architecture and cytology (fig 2) Dilated, irregularly shaped acini, lined by regular well differentiated mucus secreting columnar epithelium, are present in the lower levels of the mucosa and penetrate extensively through the muscularis mucosæ into the sub mucosal layer (fig 3) Everywhere the epithelium remains regular and cytologically benign (fig 4) There is a chronic inflammatory infiltrate by plasma cells, lymphocytes and some eosinophils in the lamina propria and submucosal layer

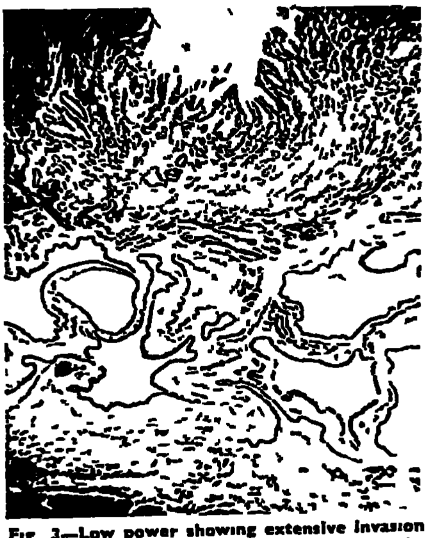

Fig 3—Low power showing extensive invasion of submucosal layer without invasion of muscle wall (× 20)

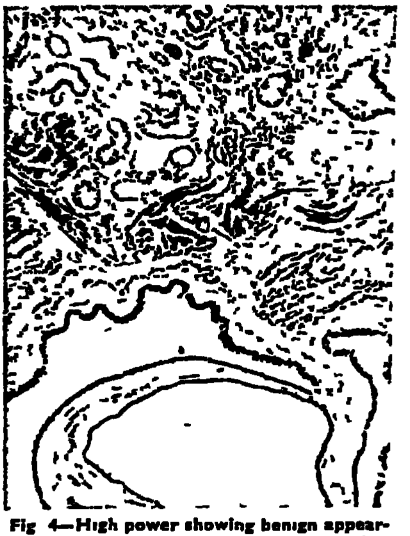

Fig 4—High power showing benign appearance of invading epithelial elements (× 70)

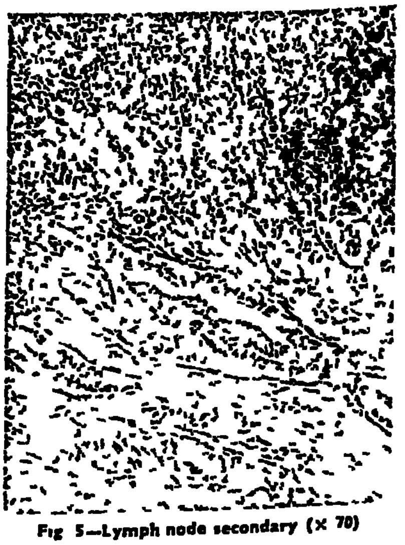

Fig 5—Lymph node secondary (× 70)

Annotations

UPPER ALIMENTARY BLEEDING

BLEEDING from the upper alimentary tract is a problem which taunts us, sometimes diagnostically and always therapeutically. During the decade 1923–32 the mortality at the Massachusetts General Hospital due to massive hæmorrhage from acute ulcer was 13%, and it remained so during the years 1938–47: in 1948–53 it had risen to 17%.[1] Methods of blood replacement have improved immeasurably since 1932 and surgery has entered the therapeutic field as an emergency measure—all to no good, it seems. In the first memorial lecture before the American Gastroenterological Association, Dr F. Avery Jones reported 39 deaths in 563 patients with bleeding from peptic ulcer during 1941–46 and 57 in 744 during 1951–54,[2] a mortality of approximately 7% in each group; and this has remained unaltered although operation was advised during the latter period for patients with recurrent bleeding, for those between 40 and 70 years old, and for those with chronic ulcers. Welch et al.[1] have shown that, in the Massachusetts series, only 8 patients were operated on in an emergency during 1923–32 and all 8 died, compared with 45 operations during 1938–47 with 22% mortality, and 100 operations during 1948–53 with 25% mortality. If the best that surgery can achieve gives a higher rate than the over-all mortality and does not reduce it, why switch to surgery? Brandon[3] is convinced that immediate gastrectomy is not the solution in the late stages of hæmorrhage, and he has had very encouraging results with adrenaline and Russell's viper venom given through a stomach tube. If excessive bleeding recurs after this treatment, Brandon repeats it as a preparation for operation.

But the results of treatment of acute hæmorrhage are confused by the increasing age of the population. The proportion of Avery Jones's patients over 60 has risen from 33% in 1941–46 to 40% in 1951–54; and Welch et al. encounter massive bleeding in patients over 70 fifteen times more often now than was the case in 1932. Moreover, ulcer associated with hæmorrhage has been twice as common as a cause for admission in all patients in their sixth decade as in their fifth; and the mortality from bleeding increases steeply with age, being almost doubled (13–25%) from the sixth to the seventh decade. Thus, increasing age has spoilt the figures and at the same time has necessitated more operations, since in the view of Welch and his colleagues the elderly tolerate operation better than expectant treatment. Though Avery Jones's surgical policy has not reduced over-all mortality, there has been an improvement in patients under 60 and in those with chronic gastric ulcer.

If operation is to be performed, it is important to determine the site of bleeding before operation; and this may be by no means easy. Common sense and a knowledge of the probabilities are a fair guide: in the Boston series œsophageal varices accounted for 32% and duodenal ulcer for 38%. It is understandable therefore that Nachlas[4] should have found it a help in diagnosis to compare gastric and œsophageal aspirations after occluding the œsophagus at the level of the diaphragm by an inflatable balloon. But his apparatus would have little application in this country; in Avery Jones's series whereas 32% of admissions were due to duodenal ulcer only 2·7% arose from portal hypertension. Avery Jones uses gastroscopy to try to find the source of bleeding and he prefers this method to X-ray investigation. Should these measures fail and the source of blood is still not revealed by a proper examination at laparotomy of the cardia, the fundus, and the mucosa through an incision into the stomach, most surgeons perform partial gastrectomy since the undetectable lesion is commonly due to small erosions hidden within the folds of the stomach so *that* no *tell tale induration* can be *felt* by the exploring fingers. But that is the kind of bleeding which Brandon has successfully treated with adrenaline and viper venom; and further experience with this method may reduce the indications for operation.

HELP FOR THE PSYCHIATRIST

DOCTORS and the community continue to learn more and more of the serious impact of mental illness on marital, social, industrial, and educational relations. As a result, an ever wider range of patients and conditions are referred to the psychiatrists, who are unable to deal adequately with all the patients sent to them. Nor are they equipped to meet the additional demands of society for guidance in the prevention and treatment of minor mental disturbance. Hopes have therefore been raised that much might be done on the spot by non-specialists if they commanded better knowledge of the working of the mind and simple psychotherapy. In this way social services would be greatly improved and a considerable burden might be lifted from psychiatric clinics.

At a meeting of the Tavistock Institute of Human Relations on June 15, Dr J. D. Sutherland described the work of a group of psychiatrists specially trained in psychotherapy and interested in the application of their work to the problems of the community. He emphasised that one of the most pressing matters facing the National Health Service was how to deal with the vast amount of illness and unhappiness caused by psychological disorders. Anyone connected with a psychiatric clinic knew only too well the depressing situation created by the gap between the available therapeutic resources and the needs for treatment. There was also the great mass of psychological ill health which did not reach the psychiatrist. In psychiatric clinics, the need for more psychotherapy was paramount: the great difficulty, as Dr Sutherland saw it, was that psychiatrists were often quite inadequately trained in psychotherapeutic skill. He did not think that increased opportunities for and training in psycho-analysis was the solution: "the therapeutic results of this form of treatment do not warrant such an expansion." At the Tavistock Clinic, therefore, attempts have been made to devise more economical psychotherapies, and group analytic methods are now offered as the main treatment to adult patients.

While general practitioners and doctors in maternity and child-welfare clinics can refer patients to psychiatric clinics for treatment, the hope of treatment there all too often proved vain. They were therefore forced to give rough and ready psychological help themselves, realising at the same time how much more they could do if only they knew how. Social workers, probation officers, social and industrial psychologists, and educationists found themselves in much the same situation. With more knowledge of psychology, they could greatly increase the efficiency of their work and often avoid sending patients to psychiatric clinics. Like general practitioners, Dr Sutherland remarked, "they too know that if they cannot do it, there is little or no chance of it being done in the overburdened psychiatric clinics."

From the number of applications received for courses at the Tavistock Clinic, it was clear, Dr Sutherland said, that many members of professional and non-professional groups were eager to increase their psychological skill. Two years of part-time training had been found to be the minimum for reasonable efficiency.

Three lymph nodes from the lesser curvature show sinus catarrh but no evidence of malignancy The cœliac lymph-node and adjacent connective and adipose tissue contain mucus secreting carcinoma, some of which is similar to, but less well differentiated than the submucosal elements in the stomach and some of which is poorly differentiated (fig 5)

The patient was well when last seen two months after the operation

I hope to follow this case in order to verify that there is no other primary from which this secondary deposit could have been derived Meanwhile, in view of the histological similarity between the better-differentiated elements in the lymph node secondary and the submucosal elements, and the fact that no other primary was noted at the time of operation it must be assumed that the carcinoma originated in the stomach

This case suggests that giant hypertrophic gastritis may not always be as benign as it is assumed to be, and that penetration of the submucosa by epithelial elements, however benign in appearance, should be regarded with grave suspicion

Ancoats Hospital,
Manchester 4

ROGER GILLETT

ANTENATAL IDENTIFICATION OF HEREDITARY DISORDERS

SIR,—Since amniotic fluid cells can be obtained from the 12th week of pregnancy [1,2] and the fluid has been shown to contain well-preserved cells from the 12th week and possibly even earlier,[3–5] the most obvious clinical value of using these cells for antenatal diagnosis would be in certain cases of sex-linked abnormalities Dr Edwards's comments (April 28) on antenatal detection of hereditary disorders raise the interesting point of using amniotic fluid cells for other purposes, such as the detection of fœtal antigens

The actual detection of fœtal antigens can lead directly to early identification of incompatibility during pregnancy, and this may be especially valuable in certain cases where the father is heterozygous It may also be useful in the field of preventive medicine, in cases of hereditary abnormalities that are genetically linked to an antigen For this latter purpose it is insufficient to have the type of linkage that has been found with the nail-patella genes,[6] since this is a linkage with the ABO group as a whole It is necessary to have a close linkage, preferably without any crossing over, between a hereditary abnormality and a particular antigen—e g, the antigen for B within the ABO group The type of linkage to seek is that found between elliptocytosis and a specific Rh combination, where in one family [7] the gene for oval cells always goes with the antigen constitution cDE In this case there is complete linkage and no crossing-over

In a list compiled in 1954,[8] of 28 characters that had been examined for linkage with blood-group genes, only 1 shows positive evidence for linkage But, as Race and Sanger pointed out,[8] this should not discourage further investigation since there are now available many more antigenic markers than could be used in most of the earlier studies It is therefore desirable that anyone collecting material on human genetics should specifically test for this type of evidence

It may be predicted that, with an increase in our knowledge of the genetics of man, there will be an increase in the use of amniotic fluid cells, and possibly even of other constituents of the fluid

HORMONES AND BREAST CANCER

SIR,—In his provocative letter last week Dr Loeser states that seaweed was used in Ancient Egypt as a therapeutic agent but wrongly makes the implicit assumption that this was a rational measure

It is now generally appreciated that Egyptian medicine comprised a curious admixture of largely empirical therapy and a strong element of magic, employing not only oral and written formulæ but amulets and similar talismanic objects The materia medica of Egypt included rather extraordinary substances and it is not surprising that seaweed should have been included

It has also been suggested that in Classical Greece burnt seaweed was administered in the treatment of goitre It cannot seriously be claimed, however, that either in Egypt or in Greece was iodine deliberately used as a rational therapeutic agent, any more than it can be said that Leucippus Democritus or Lucretius really anticipated the modern atomic theory based on experimental evidence

Edible seaweed or dulse has been utilised as a food in Scotland and Ireland, and it would be interesting to know whether there is folk-lore belief in its therapeutic application A small breed of Orkney sheep is said to subsist largely on seaweed and is claimed to have a high mutton-iodine content It would be of further interest to know whether this diet has any effect on endocrine relationship in these animals

Glasgow S 1

A T SANDISON

SIR,—Dr Loeser is to be congratulated on his letter In view of your leading article of May 12, there can be no doubt that there is urgent need for reappraisal of the treatment of advanced cancer The surgical procedures have become so radical that in many cases the cure, or palliation, must be considered far worse than the disease Adrenalectomy and hypophysectomy, the latest arrivals in the field, offer magnificent opportunities for the exercise of a high degree of surgical skill, but it would be a brave family doctor who would actually advise a patient to undergo such operations More and more, attention must turn to the endocrine control of advanced carcinoma, in preference to mutilating surgical procedures, and some attempt must be made to collect the observations and work of independent observers, such as Dr Loeser, in this field

All work on the endocrinotherapy of cancer is based on an attempt to modify the hormone environment of the tumour by injection or ingestion of hormones, or by deprivation of hormones by thyroidectomy, oöphorectomy, adrenalectomy, castration, or hypophysectomy It would appear that the success or otherwise of such methods of endocrinotherapy depends on the effect of the technique employed on the internal balance of the pituitary There is considerable evidence to show that the cause of cancer is a hypophyseal dysfunction, or hyperfunction of the thyrotrophic centre (the eosinophil cells) with a relative hypofunction of the gonadotrophic centre (the basophil cells) This hypothesis explains the success of Dr Loeser's treatment by thyroid just as it explains the success or failure of other hormone treatments

The administration of small doses of thyroid extract over a long period will diminish the thyroid secretion and the secretion of thyrotrophic hormones, and so enable the pituitary-dysfunction to be temporarily corrected There is a danger, however that the effect of this administration of thyroid will wear off, and that the original imbalance will be restored, as happens in massive testosterone therapy We all have experience of the patient with carcinoma of the breast whose secondaries disappear completely with testosterone for two or three years and then return with speedily fatal results

As well as attempting to modify the pituitary state by exogenous hormones, attention must be turned to modifying the production of endogenous hormones This can best be done by the application of short waves to the pituitary and gonads, although it is possible that future methods of treatment will be by radioactive isotopes A combination of the administration of exogenous hormones and short wave irradiations on some inoperable cases, in my practice, has

"The basic task during this period is for the trainee to learn to make adaptations in his or her own personality, in other words to get to know himself" Nothing approaching a personal analysis was envisaged—or indeed necessary After training, "an essential feature of continuing practical work is the maintenance of an easily accessible personal relationship between the various groups and the consultants at the clinic With such a permanent integration the case worker's skill has increased to a quite remarkable level, and provides a safety net for all parties, the patient, the case-worker, and the consultant" Such contact need never be more intensive than once weekly, and often much less

Dr Sutherland felt that a few specially trained consultants working in the main centres would suffice to improve local services He pictured close contact extending from the psychiatric clinic through general practitioners, public-health workers, health visitors, probation officers, social workers, marriage guidance counsellors, educationists, and teachers—to fields far removed from clinical psychiatry proper *It is to developments of this kind that the Tavistock Clinic and the Tavistock Institute of Human Relations are planning to devote* a substantial part of their efforts

FINCHDEN MANOR

IN a new book[1] with a deceptive title more appropriate to an Edwardian novel, there is a serious contribution to the literature of psychological maladjustment, and its diagnosis and treatment Written by a journalist in non-technical language, it is none the less of interest to teachers and psychiatrists as a remarkably clear and interesting account of the pioneer work of a *residential establishment* where Mr G *Lyward* has for many years been engaged on the rehabilitation of maladjusted adolescent boys Finchden Manor is designed so that boys sent away from their schools "for delinquency, or for obvious mental sickness, should have a chance of being put right, instead of being left to the further mercy of their inward conflicts and compulsions" The atmosphere of the Manor is permissive, pressures are released and a boy is allowed, often for the first time in his life, to relax and for a period of respite go his own way and do what he wants Those labouring under excessive demands laid upon them by ambitious parents, or enduring other emotional strains, find this non-demanding restful atmosphere the first stage to their complete recovery of health, spontaneity, and zest for life Guidance is offered when required, advice given when sought There is no psychotherapy as such, no elaborate individual treatment The highly unusual but largely untrained staff are always there to give emotional support, to offer a challenge or interpret behaviour, and to supply the general background of disinterested affection necessary for a boy's natural development Such a system puts severe strains upon the staff and demands unusual patience and insight The boys, too, have to be of superior intelligence if they are to be able to understand what is taking place and be able to discuss themselves and their problems objectively It is not surprising that few boys with intelligence quotients under 115 are accepted into residence

Mr Lyward's method of treatment is extremely personal, based more upon intuition and experience than upon scientific analysis Yet it does not conflict with orthodox psychiatric methods, and it illustrates the way in which therapeutic communities can be set up without highly trained or professionally qualified staff "Casualness" characterises the Lyward touch—and individual treatment (which he calls "unfairness," by which is implied not treating boys alike for the sake of superficial conformity but dealing with each according to his personal needs) So each boy sets out on a voyage of discovery of himself and of the community in which he lives, under the piloting touch of a man of genius and unusual devotion For Lyward is something of a genius and it is doubtful if the work could survive his departure

This book is a valuable companion to the recent *Ministry of Education* report on maladjusted children[2] filling in the human material on the bare bones of fact It is written from the standpoint of a convinced believer and is naturally uncritical and over enthusiastic Inevitably it will be compared with David Wills's *The Barns Experiment*, although his school at Ancrum received boys of a much lower intellectual level and generally from a poorer social background Their methods are rather similar, but Wills does not claim so high a proportion of successes as Michael Burn does for Finchden Manor Wills's book is by comparison a more balanced and objective piece of writing, and as a contribution to sociology will certainly outlive the newer book What *would have been equally valuable would have been* a book written by Lyward himself setting forth *the principles underlying his treatment, together with* a deeper analysis of his successes and failures For failures in such remedial work are as significant as the successes in that they reveal the limits of such treatment and identify the types of children unlikely to respond to it Lyward's so called "answer" to maladjustment is only one possible answer and only succeeds with some children Once that is understood, his work can be viewed in its proper perspective, as a sensitive and skilled exploration of the possibilities of the human personality's power for self healing in a secure and *loving* human environment

CIGARETTE SMOKE

IN 1936 Bogen[3] reported that during the burning of the first quarter of a cigarette the temperature of the inhaled smoke was little different from room temperature it reached body temperature only when half the cigarette had been consumed, and it did not exceed body temperature until the cigarette had burnt down to a length of about 1 cm More precise data were given by McNally[4] using thermometers placed in the smoke stream He found that smoke temperatures remained at 27°C for the first 3 5 cm and rose to 52°C when the cigarette was *smoked to* within 0 5 cm of the end He pointed out that the rapidity of smoking was important, since cigarettes smoked quickly gave a much hotter smoke, particularly when the cigarette was short

Experiments conducted by Harlow[5] in the research laboratories of the American Tobacco Co gave figures for the "coal" temperature (temperature at the burning point) of cigarettes and certain types of pipe tobacco The coal temperature of cigarettes was 774°C during puffing and 746°C during free burning The smoke *temperature 3 5 mm* from the burning end was 103 C, which means a change in temperature of more than 600°C in the 0 01 sec taken to travel the 3 5 mm As Greene[6] has pointed out, these results indicate that, in smoking, tobacco is very rapidly heated to high temperatures, and, in fact, the conditions in burning tobacco are those of thermal cracking whereby free radicles are produced and organic substances break down and recombine Greene asserts that there is overwhelming evidence that organic compounds readily yielding free radicles are carcinogenic Harlow found that the temperature of cigarette smoke entering the mouth did not exceed body temperature until the cigarette was smoked to a shorter length than 23 mm, and only 1 produced remarkable short term improvement at least equal to that from drastic surgical procedures

In July, 1938, the late Mr James Joyce, addressing the Reading Pathological Society, said

' It is my firm opinion that until cancer can be treated from a new angle such as endocrinology may provide, we cannot hope to obtain the results which will satisfy us in any field of cancer therapy "

Eighteen years later it would appear that we can but re echo his words, and hope that this branch of endocrinology will be raised to the status its importance merits

Reading W G TAIT

INTERMITTENT POSITIVE-PRESSURE RESPIRATION

SIR,—The very interesting case of respiratory paralysis described by Dr Lawes and Dr Harries (May 26) will be carefully studied by all who might have charge of such a case The methods used are known to have been inadequate and so the problem becomes twofold (1) What treatment was more likely to have succeeded ? (2) Is all the necessary equipment at hand to treat a similar case should it be admitted to our own respiratory unit ? We would like to comment on some details of the treatment used and to put forward alternative suggestions

The tracheotomy tube was probably of too small a diameter, and the shape was a major cause of death

We feel that the tube designed on this unit [1] would have given better results The metal linings are now made by Thackray, and Magill s tubes in good condition are readily available, so there is no question of special rubber tubes having perished before being wanted We have not seen any tracheal ulceration develop whilst using these tubes, and have had the added pleasure of seeing an established ulcer heal in a few days when the first of our tubes was put into service

The following tests probably explain why the infant had increasing carbon-dioxide tension even though the correct ventilation was apparently taking place as shown by measuring the air leaving the expiratory port of the Stott valve

A Stott valve was connected to a Radcliffe machine which had a gas meter recording the air intake The patient was represented by a spirometer with variable weights on the bell Expired air was measured by another spirometer, unidirectional valves and a pressure gauge were also used at times Results were variable not only when using different valves but also when repeating the same test on the same valve, but the over all picture was consistent Our conclusions were that air can pass from the inlet to the outlet without going to the patient The volume leaving the Stott valve will equal that entering the machine but will be quite different from that which reaches the patient The following are two average examples of 600 ml entering the machine and eventually leaving the valve, only 400 ml reached the " patient " Similarly of 450 ml only 300 reached the " patient " The " lost " air is thought to be compressed in the tubing during inspiration and released during expiration In clinical use we repeatedly found that the apparent tidal volume had to be maintained in the region of 50% above the figure given on the Radford nomogram, and any reduction in this volume was quickly followed by protests from the patient

When a B O C flutter valve was submitted to the same test this discrepancy did not occur We have found that the B O C valve, being made of softer rubber, produces a 2 5 cm water pressure between the machine and the valve and less than 0 5 cm water pressure in the airway whilst the Stott valve produces 6–8 cm pressure between the machine and the valve and a sustained pressure of 1 5–2 cm water pressure in the airway This may interfere with the gaseous exchange in the lungs It was found, however, *almost at the cost of a life*, that the diaphragm of the B O C valve can be inserted reversed and this should be appreciated by all who use them

Because the percentage of dead space rises as the tidal volume falls a slower rate of ventilation with increased tidal volume should have helped to reduce the carbon dioxide tension in the infant Had this not resulted, the temporary use of an efficient absorber could have been tried Whilst a circle absorber is likely to have been effective, Sandiford's [2] to and fro one is almost without dead space and so should be better With a circle absorber in use, minute volumes can be read on a gas meter

We are in full agreement that the inflationary pattern of the Radcliffe is too prolonged By redesigning the escapement mechanism we can now vary the wave pattern at will

To summarise, we suggest that the infant was receiving a deficient volume of air through too narrow a tube, and from the many tests which we have done on the Stott valve during recent months we consider the *performance* to be very variable and that it is not reasonably possible to measure the tidal volume being delivered One is left to control the patient largely on clinical observations

There is still room for considerable improvement in our knowledge of techniques and machinery Is all possible being done to pool existing experience and knowledge which is being gained *on a few isolated units* which are treating in all comparatively few patients each year ?

H B C SANDIFORD
Portsmouth Poliomyelitis Unit I MCDONALD

A CALCIUM-INFUSION TEST

SIR,—Dr Nordin and Dr Fraser, in your issue of June 2, record an experiment in which 98 patients, including " 21 patients in whom there was no reason to suspect metabolic bone disease " and " 30 patients with miscellaneous conditions in which bone disease might be suspected " were subjected to a four hour intravenous infusion

Would it not be a good principle to state clearly in all accounts of experiments utilising human controls that the human *controls* are volunteers and to record the means by which their cooperation was achieved ?

London N W 5 ANTHONY RYLE

***Dr Ryle's letter has been shown to Dr Russell Fraser whose reply follows —ED L

SIR,—Both the preliminary and other subsequent tests of the intravenous procedure described were performed on volunteers amongst the research team With all patients, agreement to the performance of the test procedure was of course obtained Those not initially suspected of bone disease willingly *gave their* consent We had every reason to believe, from personal experience, that the test was devoid of any risk, and in fact no untoward symptoms or effects followed the test in any instance

Postgraduate Medical School,
London W 12 RUSSELL FRASER

ANTENATAL CARE

SIR,—" A concerted effort against toxæmia of pregnancy " need not involve " the chairmen of boards of governors, and of hospital management *committees*," as implied by the Ministry memorandum to which you referred last week

It must involve the careful study of the prevention of Eclampsia and Pre Eclampsia [3] wherein R H J Hamlin sets out the " seven steps " by means of which he eradicated eclampsia at the Women's Hospital, Crown Street, Sydney, together with *acceptance* of his two points (*a*) early detection by weight increase between 20th and 30th weeks, and (*b*) institution of a high protein, high vitamin, and low carbohydrate diet at that stage

The Ministry's memorandum pays lip service to Hamlin (" in Australia the practice of the Women's *Hospital*, Crown Street, Sydney, described by Hamlin "), but further on states " *a routine designed to detect the* smallest deviation from the normal, for example, a rising blood pressure slight œdema or unduly rapid weight smoker in 1000, he estimated, smokes cigarettes to that length Though Greene gave figures for the coal temperature of pipe tobacco 200°–300° lower than that of cigarettes, Harlow maintains that the coal temperature of pipe tobacco can be even higher than that of cigarettes because of the pipe-smokers' habit of taking several small puffs in a very short period

BREATH-HOLDING ATTACKS

PARENTS usually agree that their children are most "difficult" during the toddling and preschool years Negativism, temper tantrums, sleep disturbances, and sphincter troubles are at a peak, and there is little reassurance in being told that all children have behaviour problems No doubt the child is also finding his parents difficult too and he will hardly be consoled by the fact that his parents' intolerable and inexplicable attitudes are normal Breath-holding attacks are one of the most alarming manifestations of inter-personal tensions during this period Although they are by no means rare they are often correctly diagnosed only after much anxiety and unnecessary investigations Perhaps it is their rarity outside the home which has made many doctors unfamiliar with them

Hippocrates[1] was apparently familiar with breath-holding and there have been many excellent clinical descriptions since One of the best is quoted by Sir Robert Hutchison[2] from a letter written to him by an observant grandmother

> "The boy seems a thoroughly healthy little fellow, is just two, but he has a kind of choking fit The doctor has never happened to see him in one (as he does not choke to order), and I do not think understands the cause of them The symptoms are these sometimes when he is thwarted he draws in his breath to cry, but no sound comes, and he gradually turns blue about the lips, his throat seems closed Cold water is dashed on him sometimes for quite a long time At last he gasps, then goes limp and unconscious, after a short time he revives, has a good cry, and gets better"

The more detached observer, while not attaining her vividness, might have amplified and slightly amended this description Fear and fury, as well as frustration precipitate attacks But the stimulus may not always be psychic, sharp pain, a fall, or any sudden trauma set off attacks After a few cries the breath is held in expiration, cyanosis ensues and later gives way to pallor and unconsciousness If the attack is further prolonged before it is relieved by inspiration, a typical epileptic convulsion occurs This is usually quite brief and is seldom followed by postictal confusion or sleep

Current ideas about breath-holding attacks have lately been well reviewed by Zellweger[3] and by Hinman and Dickey[4] The confusion that existed in the past between breath holding attacks, idiopathic epilepsy, and laryngismus stridulus has been clarified Zellweger stresses the "neurovegetative instability" of these children and their parents—a presumably constitutional state which is not widely accepted in this country Hinman and Dickey believe that breath holding attacks are a primarily emotional disorder symptomatic of profound insecurity in the child Most of the children are between six months and five years and it is generally agreed that the disorder is self-limiting A history of pertussis is not uncommon, the paroxysmal cough and laryngospasm of that disease may in some way condition an abnormal respiratory response, as Bridge et al[5] suggested

Diagnosis is not difficult from a detailed history. The attacks are always preceded by a typical stimulus, and the sequence of events and brief duration are characteristic Some confusion with epilepsy is understandable, but the breath-holding infant who has an epileptic fit due to self induced cerebral anoxæmia[6] is no more likely to suffer from epilepsy than the adult whose fits are induced by electroconvulsive therapy or convulsive drugs While the doctor must recognise the identity of the fit in severe breath-holding attacks, there is no indication whatsoever for the prescription of anticonvulsants nor should the word "epilepsy" be mentioned to the parents Electro encephalography is not helpful except in the rare case in which both epilepsy and breath-holding occur in the same child

The management of the condition may be difficult The parents are usually relieved to know that the attacks are not dangerous, nor symptomatic of grave nervous disease Neither they nor the child are helped by giving in to every demand of the child nor by trying to stop the attacks by slapping the child or pouring cold water on him Reassurance and a sympathetic regard for the whole emotional background will do most good in preventing attacks Provided that the child receives security and affection in proper measure the attacks themselves are best treated with apparent unconcern When security and love are clearly lacking, the whole family needs guidance As Culpeper[7] wrote, "There is a disease in children from anger or grief, when the Spirits are much stirred and run from the Heart to the Diaphragm forceably, and hinder or stop the breath Sometimes they have a shrill voice the Spirits suddenly breaking forth, but when the passion ceaseth, this Symptom ceaseth"

PRELUDE TO RESEARCH

Dr William B Bean[8] offers salutary advice on how to embark on research The first necessity is that there should be an idea He has no use for "the dragnet and grappling hook approach which hopes to bring up from the murky waters whatever body may be floating about, if there is one" but which too often brings forth only a monstrous array of papers without ancestors or descendants Rather should the aim be to produce, after a piece of thoughtful work a paper which adds a sound brick to the growing edifice of knowledge

Ideas cannot be generated at will they come from wide general information and intense and thoughtful observation, with meditative rumination often at inaccessible levels They tend, moreover, to be fleeting, and they should therefore be committed at once, briefly but intelligibly, to a notebook, from which, at the first opportunity, they are transferred more elaborately to a commonplace book Before starting an investigation the worker should demand of himself a clear statement (broad in aspect but narrow in detail) of its purpose The construction and subsequent study of such a statement may show the idea to be unsound, the method unsatisfactory or the work not worth doing—conclusions far better reached now than later All data should ultimately be recorded in a bound recording book, or at any rate the folder, drawer, or cabinet number of the original crude data should be recorded Bean favours Hale Ham's procedure of making an experimental protocol—a clear, brief, permanent record permitting exact duplication in the future, and containing data sufficient for publication *Biological material*, reagents, and apparatus—especially any departure from standard equipment—should be fully described *Actual procedure* is the crux of the experiment, the details of which should be set down so precisely that it can be repeated readily by anyone conversant with the subject "A compulsive neurosis, conditioned by active and critical thought, seems to be the occupational prerequisite of the investigator" gain" One realises, as no mention is made of what action he took when the 'smallest deviation from the normal" was detected that his vital point—dietetic control—has been missed In 1952 Hamlin outlined the progressive stages to eclampsia

ANÆSTHESIA IN OBSTETRICS

SIR —Anæsthesia for the application of forceps, in addition to the danger of inhaled vomit diminishes the mother's expulsive forces and also impairs fœtal vitality Why therefore, should these disadvantages be courted when analgesia is sufficient ?

Devonport,
Plymouth O LL LANDER

DEADLY SWEETS

SIR,—In your annotation of June 9, referring to a further case of ferrous sulphate poisoning, there is an unfortunate contradiction in advice In one place you state "The problem of accidental poisoning will not be solved by reproaching the manufacturer" But further on one reads -

> 'The replacement of all attractively coloured and flavoured drugs of potential danger by something less deceptively decorated is long overdue, and is the most effective single step we can take towards preventing these tragedies"

There is hope that this further case of iron poisoning may stimulate the manufacturers to issue these tablets in 'Cellophane' envelope strips but your statement that the manufacturers should not be reproached may reduce the likelihood of their coöperation Surely this further tragedy should force us all to redouble our efforts with the manufacturers, as well as to increase the knowledge of the general public on the subject

Plymouth HUGH JOLLY

SIR,—In your annotation you say The replacement of all attractively coloured and flavoured drugs of potential danger by something less deceptively decorated is long overdue " Influenced by similar earlier comments in your own and contemporary journals, and by a resolution of the Pharmaceutical Society, my company issued and made widely known to the profession a white and virtually tasteless form of tab ferr sulph co *N.F* I understand we were not alone in such action The continuing demand, however, is for the coloured sugar-coated tablets the white ones are not wanted I cannot feel that so many thousands of prescribers are without sound reasons for their preference

Evans Medical Supplies Ltd
Speke Liverpool C W ROBINSON
Director

RUPTURE OF THE SPLEEN

SIR —Your annotation last week refers to various diagnostic radiological features In a case recently admitted to this hospital, Howell-Jolly bodies appeared in the peripheral blood, and before laparotomy I strongly suspected a lesion of the spleen

A woman, aged 57, was admitted for observation following a car accident not at that time having any definite evidence of injury Three days later she collapsed and complained of abdominal pain Examination of the blood showed numerous large polychromatic red cells many of which contained Howell-Jolly bodies At laparotomy the same day a ruptured spleen weighing 300 g, together with blood-clot was removed, there having been a hæmoperitoneum There were subcapsular and intrasplenic hæmorrhages Histological examination failed to reveal any evidence of glandular fever or of any other lesion likely to lead to rupture

Howell-Jolly bodies are known to appear after splenectomy and in certain diseases but I had not previously been aware that their appearance might precede splenectomy in cases of injury In the present case a possible explanation is that a form of 'auto-splenectomy' took place owing to pressure of the various hæmatomata on the splenic vein and interference with venous return from the spleen

I suggest that examination of the blood for Howell-Jolly bodies may be useful in cases of injury in which abdominal and particularly splenic lesions are suspected, but in which laparotomy is not immediately desirable

PARAPLEGIA FOLLOWING SPINAL ANÆSTHESIA

SIR,—It becomes almost embarrassing when a university professor of anæsthetics persists determinedly in appearing completely simple in this problem of the unexplained perils inherent in spinal anæsthesia, and ignores the issue raised by the two propositions (1) that the only known common factor in cases of neurological complications ensuing upon spinal anæsthesia is the intrathecal introduction of an anæsthetic substance, and (2) that the immersion of ampoules of such substances before use in toxic solutions is not such a common factor

It may be taken for granted that in an important university department such as Sir Robert Macintosh's at Oxford there is an adequate bibliography of the very numerous instances of neurological disaster ensuing upon spinal anæsthesia Nothing less could be expected of a department the head of which has felt himself able to publish a monograph upon this technique for the instruction of his colleagues

He must have at hand the information needed either to lend some cogency, if this were possible, to his umbrella hypothesis of the cracked ampoule or, alternatively, to reveal its large irrelevance

Can we not persuade him of the expediency, if not of initiating some fruitful research upon this question, at least of providing a comprehensive and dispassionate review of all the known facts and hypotheses up to date ?

Surely it is not unreasonable to ask of a university department responsible for research, for teaching and for setting an example of practice in its own field, something more academic and serious than the collection of three out-of date anecdotes about cracked pots

London W 1 F M R WALSHE

SIR,—In the early days of my 'chemical sympathectomy," produced by paravertebral injection of a 10% aqueous solution of phenol I had one case which is of interest in connection with this subject

An obese woman was given a paravertebral injection of 10 ml of 10% aqueous phenol solution at the level of L3

The Casualty Department

II SHORTCOMINGS AND DIFFICULTIES *

T G LOWDEN
B M Oxfd, F R C S
CONSULTING SURGEON, SUNDERLAND GROUP HOSPITALS

THE work of the casualty department has been outlined Some of the difficulties facing its medical and administrative staff can now be considered

Medical Problems

Lack of Continuity

Where a junior medical officer, a rota of such, or a rota of general practitioners is responsible for the care or disposal of casualty cases, one of the greatest disadvantages is lack of continuity of medical care An unsupervised appointment lasting six months or a year, or an attendance at the clinic once or twice a week, gives little opportunity for the doctor to acquire skill, to explore new methods, or to assess late results There have been great improvements in the treatment of many types of casualty case in recent years, and under the present system these changes have little chance of affecting many of the patients

Shortage of Staff

In a health service already seriously understaffed with junior medical men the relative unattractiveness of an appointment to the casualty department has resulted in a great shortage of casualty officers

Before the establishment of a nationally controlled health service criticism was restrained by an appreciation that much of the hospital system was provided by voluntary effort Since this establishment there has been no such restraint, and although the increase of complaint and attack has done a certain amount of good, it has often been unjust and irresponsible Casualty departments are particularly liable to suffer from complaints Most of these are about delay in attention to minor cases, and this is often unavoidable in an ill designed department where, during certain parts of the day, the speed of arrivals far exceeds the speed with which attention can be given The more serious ones refer to occasions when major injuries or urgent medical conditions have to wait The usual reason for this is lack of medical cover, sometimes because the establishment does not allow of a doctor being constantly in the department, and sometimes because, although the establishment is adequate, it has been impossible to find doctors to complete it

Fear of Legal Action

The increase in litigation against the hospital services, and in the amounts awarded in damages, are making all doctors careful about exposing themselves to legal action , and because casualty departments are particularly liable to such actions, appointments to them have become even less popular than before Those who accept such appointments find that their clinical decisions are increasingly modified by this situation Consequently many patients are admitted for observation and are investigated unnecessarily

Some administrative bodies, with this in mind, tend to appoint officers of more seniority and aim to make consultant surgeons ' responsible " for the work of the casualty department What this " responsibility " entails is at present obscure If a consultant is to have any practical effect on casualty work it will take a great deal of his time To make him merely " responsible on paper " may relieve the anxieties of administrative authorities for a time, but it will confer little benefit on the patients, and will do little to reduce the margin of error in the clinical work Nobody can be " responsible " in the medical sense, when engaged elsewhere

Clinical Standards

Clinical results can be vastly improved by applying to the minor surgical problems of the casualty department principles which are generally applied in inpatient surgery Clinical response partly depends on starting treatment as soon after the injury or the onset of the disease as possible Two days' delay for a septic hand may mean an extra two weeks' incapacity Holding a weekly consultant clinic does little to combat this

Economy of Staff and Money

With the establishment of routine consultation and dressing techniques the long queues of repeat attendances which begin the day's work in most casualty departments can be reduced , and if some assembly line system is adopted, in which all ambulant patients pass successively through records, medical, and nursing stations, each one can be dealt with more quickly Such a casualty service needs at least one doctor and corresponding nursing and clerical assistance Bacteriological and radiological services are essential, and so is adequate space designed to allow transit through entrances, waiting and treatment rooms, and exits without congestion

It is neither an economic proposition nor would it be possible at present to establish such a department in every hospital in the country For this to be justified a turnover of about 10,000 patients per annum would be needed 20,000 patients would require at least two doctors, but considerably less than twice the other facilities, and from this point of view a concentration of casualty work might appear to be a simple solution However, any attempt to merge a number of smaller units into a single large one has inherent disadvantages

1 Some of their functions, especially those of reception and disposal, cannot be divorced from the other functions of the individual hospitals

2 Where a local department is absorbed into a central, patients have to travel further , and because many of them suffer from trivial complaints, they are less likely to go to this extra trouble It is useless trying to encourage early attention and at the same time making it harder for patients to get it

Pilot investigations on the economic impact of minor injuries and sepsis indicate that a working man may cost the Exchequer £5–6 a week when he is incapacitated, and that his loss of earnings amounts to £3 more[3] The global sum cannot at present be estimated, but must be counted in millions It is possible, by improving medical and nursing cover, to reduce this by a significant amount From the point of view of national expenditure, therefore a nation-wide improvement in the casualty service would repay the outlay of a large sum It would, for instance, pay the Ministry of National Insurance and Pensions, were they to hand over to the Ministry of Health £1 million a year, earmarked for this purpose alone Their own payments in benefits would come down by more than this It would pay the big industrial undertakings to finance improvement in the casualty departments of their own areas, and many of them did so generously before the " appointed day " It is another occasion for that popular rhetorical question " We may not be able to afford it, but can we afford *not* to have it ? "

[3] Wilkes R *Brit J industr Med* 1954 11 260

vertebra Within a few minutes paraplegia developed with sensory loss up to T6 segment Lumbar puncture was carried out and a clear fluid smelling strongly of phenol was obtained Chemical tests confirmed the presence of phenol The paraplegia wore off in three hours, but the patient had weakness of the quadriceps femoris on the side of injection which took three months to disappear

It would seem that the needle must have entered an intervertebral foramen and pierced the dura, although no cerebrospinal fluid dripped from it and test aspirations were negative The weakness of the quadriceps is explained by the high concentration of the phenol round the spinal nerve roots emerging at the site of injection

This case has been the only one with neurological complications out of several hundred treated personally by such injections, and it certainly emphasises the need for great care when carrying out paravertebral injections of potent fluids In addition, it indicates that a considerable amount of phenol can be introduced intrathecally without lasting damage to the spinal cord In the light of this evidence it seems most unlikely that an ampoule of spinal-anæsthetic fluid immersed in 5% phenol solution could absorb, through microscopic cracks, enough phenol to cause a permanent paraplegia when injected intrathecally As Sir Francis Walshe indicates (June 2), the only common factor in the reported cases of paraplegia after spinal anæsthesia is the use of a spinal anæsthetic, and it seems clear that the risk of such a tragic complication is inherent in the injection, no matter how perfect the technique of its administration

Manchester HERBERT HAXTON

CAUSE OF HYPOGLYCÆMIC SYMPTOMS

SIR,—In your interesting annotation of June 9 you state that it is hard to estimate the significance of our finding that sweating still occurs in response to hypoglycæmia in patients after thoracolumbar sympathectomy It should be made clear that sweating was only seen in the regions such as the face and upper limbs, not affected by the sympathectomy No sweating was seen in the regions denervated by the operation However, the point at issue is whether sweating still occurs when, owing to adrenal denervation, adrenaline is not liberated The persistence of sweating in these patients is thus further evidence that adrenaline plays no part in sweating due to hypoglycæmia

The lack of correlation between adrenaline release and occurrence of sweating is demonstrated in several other observations You mention the fact that intravenous infusions of adrenaline do not produce sweating It is also of interest that the sweating which is a conspicuous feature in a patient with a phæochromocytoma may persist for several days after removal of the tumour,[1] and clearly it cannot be due primarily to the excessive liberation of adrenaline

Sheffield R KILPATRICK

BUTALITHONE SODIUM IN ELECTROCONVULSIVE THERAPY

SIR,—It may be of interest to mention our preliminary experience with butalithone sodium ('Transithal,' 'Ulbreval') as a substitute for thiopentone sodium in anæsthesia for electroconvulsive therapy

We have found that butalithone sodium, in a dose of 0 25–0 5 g given intravenously over half a minute, depresses respiration less than does thiopentone, so that usually inflation is unnecessary The patient speedily returns to a safe state of consciousness, so that a junior nurse may be left in charge, and the interval before full recovery is very considerably shorter, so that less time is wasted in waiting both by patients and staff in a busy outpatient department

In our experience, extending over several hundred cases, side effects, such as hiccup and retching, have been no commoner than with thiopentone

APPENDICECTOMY DURING GYNÆCOLOGICAL OPERATIONS

SIR,—British gynæcologists have always been somewhat doubtful about the advisability of routine appendicectomy when performing hysterectomy or other abdominal gynæcological operations Some British surgeons, however, and many Americans[1] include appendicectomy as a routine The late Victor Bonney always advised against routine appendicectomy, and obedience to the principles of this great master has caused me regret on only 3 occasions in which acute appendicitis followed within one week of hysterectomy, involving the patient in a further emergency operation I have seen a similar complication twice after vaginal hysterectomy In 1 of these patients a gangrenous appendix with peritonitis was removed forty eight hours after operation, and in another a chronic pelvic abscess involving the right fallopian tube and ovary developed and was operated upon three month after the original procedure

The great argument against routine appendicectomy has been the danger of disseminating infection from the bowel wound in the cæcum into the recently exposed cellular planes of the retroperitoneal space It is certainly true that the pelvic peritoneum recently traumatised by the operation of hysterectomy has not the same ability to resist infection as when the pelvis is intact It is possible, too, that the pelvic peritoneum is already fully occupied in dealing with the contamination from the vagina inherent in total hysterectomy and that the two portals of infection may, in certain instances, prove overwhelming

Although it is interesting to speculate on these possible sources of infection, I felt that, if exact information could be obtained from a representative number of British gynæcological surgeons, the results might be helpful to those who, like myself, wonder what is the best and safest procedure A questionnaire was, therefore addressed to 31 surgeons, and their replies are summarised below

(1) Do you remove the appendix as a routine when performing hysterectomy ?
No 26, *Yes* 5

(2) Have you seen any complications as a result of this operation, such as peritonitis, intestinal obstruction &c ?
No 25, *Yes* 6 (burst abdomen 1, peritonitis 7, intestinal obstruction 1, *Escherichia coli* infection of wound 6) (Of the 6 replying 'yes," some had seen more than 1 complication—hence the discrepancy in the figures)

(3) Have you encountered any complications from not removing the appendix ?
No 30, *Yes* 1 (a case of appendicectomy after myomectomy followed by fatal peritonitis)
Of these 'noes," 7 recalled patients in whom appendicectomy was necessary within a few months of the hysterectomy There is no evidence to connect the hysterectomy directly with the appendicitis—i e, it did not occur within one month of the operation, as in my cases

(4) Can you give me any references to any published work on this subject ?
The replies to this question were an almost universal blank, apart from the figures published by the Royal Society of Medicine in 1949 from the Samaritan Hospital, London

(5) Any other observations ?
Of the 26 surgeons who do not routinely remove the appendix, 16 made the observation that they would

what he would say to the practice which some hospitals have to adopt, of sending for a technician to perform this work after hours "

It is true that I used similar words during the debate following Dr Loutit's address to the Medico Legal Society last May, but I should like to amplify that by quoting further from the report in the *Medico Legal Journal*[6]

> I asked the lecturer if he agreed that " cross matching and grouping should never be undertaken by any doctor unless he had had adequate training and experience in this highly technical and potentially dangerous procedure " Dr Loutit replied that " he would say that cross matching should be done by the most expert man available and if he was in bed he was available " This would appear to include a competent technician who might well, as Dr Shillitoe says (Jan 7), have more expert knowledge and experience than a junior house officer of the hazards involved
>
> Dr Loutit also said that " he could see that under certain circumstances it might be right that a house physician, even although technically unskilled, should make the best possible attempt to do the grouping and cross matching It is a case of balancing the hazards, when in the absence of a transfusion the patient would die "

Dr Discombe's book[1] will be invaluable to resident doctors confronted with this difficult decision, and I hope it will be made freely available to them by all hospitals where such cases may arise

DISTURBANCES OF CARBOHYDRATE METABOLISM CAUSED BY ALCOHOL

SIR,—The observation by Dr Hunter, Dr Merivale, and Dr Smith (Dec 31) that " disturbances of carbohydrate metabolism, shown by the two dose glucose-tolerance and the pyruvate metabolism tests, were found in 7 alcoholic patients " confirms the results reported by K C Murfitt and myself to the Association of Clinical Pathologists in October, 1954 Our results were based on investigation of 47 male and 17 female alcoholics in 1953 (group I) and 42 male and 12 female alcoholics in 1954 (group II), all under the care of Dr M M Glatt at Warlingham Park Hospital In our paper we said

> " The patients of group I of both sexes had had vitamin-B_1 treatment when their blood was examined Of the men, 42 were tested and none showed an abnormally low value Indeed, a number showed abnormally high values—evidence of more than adequate medication Of 15 group I women examined, 4 had abnormally low cocarboxylase values In 1 case thiamine deficiency was confirmed by an abnormal response of the blood pyruvate to glucose administration In spite of an adequate cocarboxylase level, 14 of 46 group I men had high blood pyruvate levels, suggesting that the mild exercise they had taken to reach the laboratory had overtaxed their not fully recovered cocarboxylase mechanism Similarly, 5 of 16 women of group I had high pyruvate values
>
> " The patients of group II had not had vitamin B_1 treatment and were all bled fasting and in bed All had normal pyruvates 2 men and 5 women had abnormally low cocarboxylase values
>
> " These results indicate that this type of alcoholic is prone to add thiamine deficiency to his liver dysfunction "

Our methods of conducting the pyruvate-metabolism test and of estimating blood-pyruvate were the same as those of Dr Hunter and his co-workers We estimated blood cocarboxylase, which is a measure of the body's thiamine status, by the method of Kay and Murfitt[7]

IN THE MENTAL HOSPITAL

SIR —One imagines that our predecessors in psychiatry of a hundred years and more ago would have been encouraged and perhaps amazed to see that some of their beneficial ideas even today required emphasis, and perhaps re discovery, in the pages of your journal May I quote, for example, from the case notes of Frederick Needham, describing his treatment of one Susan Appleyard

> This girl was admitted to this hospital in 1853, when she was 20 She was described then as restless and laughing unmeaningly, and by 1858 she had sunk, it is stated, into a state of the most complete dementia , wherein she lay coiled up, moaning dismally Needham wrote on March 28, 1859 " This case is unchanged She still pulls her dress over her head, and lies coiled up in corners of the room "
>
> On April 12, 1859, Needham wrote " I this morning went into the gallery and made her—opposed a good deal at first—allow herself to be washed, her hair to be brushed, and then took her with me at first by main force into the gallery and garden I walked her about for about half an hour in the garden, had her dressed in new petticoats, a new dress, new boots and new stockings, and placed her in a superior gallery in a chair, before a table on which there was dinner, and put a knife and fork into her hand, telling her that I should insist upon her doing everything she was told, and should if need be make her do so I also said that she had to come amongst ladies and into a better gallery, and that therefore she must behave herself as she should in better society and in better apartments She ate her dinner quietly, spoke sensibly evincing much more intellectual power than one would have supposed her to possess, and then as soon as the meal was concluded she proceeded, and with much dexterity, to wash up the plates etc There was no more drawing up of the dress, no more lying down, but she conducted herself to the surprise of everyone well and correctly Her treatment thus commenced, I purpose continuing, and have ordered the attendants to never let her lie down or have her dress up, to give her a good bed , to take her each night to the water closet before bed time , to take her into the garden and greenhouse daily, and to get her to work as much as possible , to call her Miss Appleyard and to treat her as if she were quite changed Should the treatment in this case succeed it will be one of the best instances of humane and kind moral treatment as successful in cases even of the most confirmed and degraded dementia, and will indeed endorse the old *motto*, applicable also to insanity, nil desperandum "
>
> A year later Needham referred to this patient as " clean, quiet and orderly in her habits , looks well and is cheerful, happy and contented "

Needham was an unusual man, and one might take many examples from his notes and his reports of practices which have been more recently regarded as modern for example, the use of water-colours as an adjunct to occupational therapy, and the establishment of a patients' discussion club, which met fortnightly in the hospital, and which indeed published abstracts of its meetings in the hospital periodical called *The York Star* Needham, who pointed out that this printed publication owed its origin to the earlier issues of a patients' journal both at Morningside and at Dumfries Asylum, commented

> " Literary efforts of this kind, which now form so important a feature in the moral treatment of the insane, are useful not only as a means of employment and mental exertion, leading to the evolution of coherent ideas and the interruption or repression of morbid trends of thought , but because they furnish subject matter for general conversation and in this way beneficially influence a wider circle than that immediately engaged in them "

All was grist to Needham's mill, from his contemplations on the possible use of powdered charcoal as a deodorant in the long-stay wards to his more general reflections on the hospital and lunacy policy

There is, however, one short sentence of his, taken from his 1871 report, which may perhaps sum up both our current conceptions of the " therapeutic community " in a mental hospital and former ideas of the "moral treatment" of insanity This sentence reads "The insane man is too often a sane man decivilised, and to him the various processes of civilisation have again to be applied"

Bootham Park, York ARTHUR BOWEN

PULMONARY EMBOLISM

SIR,—In your leader of Dec 31 there are statements which are at variance with experience in this hospital and which I fear may be misleading

You state "that most lethal emboli strike with dramatic suddenness, bringing vicious chest pain and hæmoptysis before any diagnosis of limb thrombosis has been made" It is true that many fatal embolisms occur without recognised warning, but surely chest pain and hæmoptysis are not signs of the rapidly fatal embolism but rather of the embolism which the patient survives, and depend on the development of local congestion and pleurisy Although many embolisms, as you say, are almost instantaneously fatal, there are others in which death is delayed for a few hours and may be averted by treatment If anything useful is to be done for these patients the diagnosis should be made and treatment started at once In my experience neither pain nor hæmoptysis is to be expected in the early stages after a large embolism The important features of such a case are sudden collapse and signs of obstruction in the right side of the heart

Of more importance is your statement that there is statistical evidence for the view that "as it is the first embolism that kills, if the patient survives he has little to fear from later ones" You do not give the source of this evidence, but in an investigation which was undertaken in this hospital and reported in your journal before the introduction of current methods of treatment,[1] out of a total of 157 pulmonary embolisms only 34 were fatal in the first attack Of the 123 survivors of an attack of embolism 10 died of subsequent attacks A mortality-rate of 8% in the survivors of the first embolism can hardly be regarded with equanimity

University College Hospital,
London, W C 1
R S PILCHER

HEALTH CENTRE OR GROUP PRACTICE?

SIR,—The main point we wish to make appears to have been missed by Dr Stephen Taylor (Dec 31) The provision of premises for group practices is being hindered by such persuasive statements on what constitutes the needs for "efficient general practice" as Dr Stephen Taylor has put forward He says that anything less costly than the Harlow centres can be got only by making "real sacrifices in efficiency"—which implies that health-centre practice on the Harlow scale is in fact the cheapest efficient way of conducting general practice As a group of some years' experience we beg to differ

We omitted to say in our first letter (Dec 17) that about 60% of our finance was required for new building The remaining 40% comprised the purchase and the rebuilding and adaptation of an existing house Had a suitable central site been available for new building, our cost per patient at risk would have come down further by three or four shillings

We have no intention of criticising the Harlow centres, but Dr Taylor's arguments are liable to make general practitioners and planners believe that nothing less will do, and that much which is inessential has received the stamp of approval and therefore must be essential

In our earlier letter we showed that the widely publicised de luxe standards in premises for general medical practice can be stripped down to basic and economically achievable proportions—to 13*s* 3*d* as against £1 per patient at risk We know that just like us, there are groups of doctors up and down the country working without sluice or specimen examination rooms, and without a hall for a waiting-room or pram shelter —and working in excellent harmony with local authority services without special rooms for antenatal and baby clinics

Let the Nuffield Trust carry on its wonderful work, but it should not be thought that less costly ways are necessarily less efficient

MENTAL HEALTH SERVICES

SIR,—In your note on a New Occupation Centre in Leeds for Mentally Handicapped (Dec 31), Dr Z P Fernandez, chairman of the Leeds mental health services subcommittee, is quoted as saying that Leeds spent more in the mental-health field than any other local authority in the country, averaging £103 per 1000 of population as against £7 or £8 in other areas All credit to Leeds for its fine record in mental health—but the statement does scant justice to other local health authorities The average annual expenditure on mental health services for county boroughs in England and Wales is £44 12*s* per 1000 population, and the only authorities with an expenditure as low as £7 or £8 are a few Welsh counties and one Welsh county borough

Dr Fernandez also states that Leeds has the highest ascertainment record in the country Leeds has 3 8 known mental defectives per 1000 population, of whom 3 5 per 1000 are "ascertained" cases In Bristol the figures are 4 15 per 1000 and 3 8 per 1000 respectively Is mental deficiency really more prevalent in Bristol, or have we a higher ascertainment-rate? I wonder!

H TEMPLE PHILLIPS
Chief assistant medical officer of health

Department of Public Health,
Tower Hill, Bristol, 2

MYXOMATOSIS

SIR,—Your annotation of Jan 7 calls for certain criticism It suggests that the immediate result of the deliberate spread of this plague is an increase in the yield in rabbit-free areas and that the eventual gains could be much more striking But surely these figures are drawn from the returns last year when the weather conditions were abnormally favourable, while certain farmers may have profited in this way, others, to whom the rabbit was their livestock, have lost heavily

When to the balance sheet is added the price of inferior dead rabbits imported for food at a very much enhanced price as a substitute for the good rabbits wantonly destroyed by disease, when our merchants are paying 22*s* per dozen for foreign rabbit pelts which they formerly bought for 6*s*, when we realise that the rabbit was a plentiful, cheap, and wholesome supply of meat for farm workers and others throughout the land, competing with the high prices for other meat, surely we must think again before we put an undue assessment on the value of myxomatosis

Recently a scientific farmer, the gist of whose paper is in favour of myxomatosis,[1] has stated that as the result of it we see farms, where the rabbits were the livestock and livelihood of the farmers, "now empty warrens, whose ill fenced and ill watered lands are poorly adapted to sheep and inhospitable to cattle—sheep and cattle which many of these farmers cannot afford to buy", while your annotation admits that "our wild rabbit has qualities that will almost certainly ensure its survival both myxomatosis and hordes of rabbits may be permanently with us"

We then read that "To avoid this and to increase food supplies, the Minister of Agriculture is pressing on with the designation of rabbit clearance areas in which occupiers of the land must destroy the rabbits or, if this is impossible, prevent their causing damage" The Ministry of Agriculture has

remove it if, on inspection, they found it to be diseased, to look unhealthy, to be kinked, to be adherent retrocæcally, or to contain fæcoliths A few commented that appendicectomy undoubtedly increased the risk of postoperative pyrexia and infection and that it was a complicating factor in the convalescence after hysterectomy

---

[1] Pilcher R S *Lancet*, 1939 ii, 629

[1] *Birmingham Post*, Dec 17 1955

As a result, the following suggestions can be made

(1) That British gynæcologists by a majority, do not advise routine appendicectomy when performing hysterectomy

(2) That this rule should not be followed unreasonably and the appendix if obviously diseased or unhealthy, or if containing fæcoliths, is probably best removed

(3) That there is a real danger of local and general peritonitis, and that simultaneous appendicectomy and hysterectomy should be covered by a course of postoperative antibiotics

I acknowledge the kind coöperation of the members of the Gynæcological Travellers' Club and other colleagues who kindly answered my questionnaire

St Bartholomew's Hospital,
London, E C 1 JOHN HOWKINS

FATS AND DISEASE

SIR,—Dr Sinclair's letter (April 7) intrigues me In 1952 and subsequently we reported studies, begun in 1950, which showed a profound decrease in plasma cholesterol and phospholipids, in patients maintained on diets containing large amounts of unsaturated vegetable fats[1 2] Among the possible reasons for such an effect were considered (1) absence of cholesterol, per se, (2) a positive effect of some vegetable sterol, (3) a positive effect of vegetable phospholipid, (4) a positive effect of one or more fatty acids present in the vegetable fat

Over the intervening years, by a process of exclusion, all except the last have been essentially eliminated Studies in which fats of vegetable origin, but of very different iodine number, have been alternated in the diet have shown that the decrease in plasma cholesterol and phospholipid levels is directly related to the amount of unsaturated fat present in the diet[3] A very recent study, in which 100 g of a synthetic triglyceride, containing approximately 2 g of linoleic acid, has been administered daily,[4] further implements this conclusion

Dr Sinclair's observations regarding abnormal deposition of lipids in the skin under conditions of essential-fatty-acid deficiency are of considerable interest, as are his speculations regarding the very possible rôle of essential fatty acid and/or pyridoxine deficiency in the pathogenesis of degenerative vascular disease. His observations regarding increased requirement for essential fatty acid in male animals may be particularly pertinent in this regard

The work of Shapiro and Freedman[5] on the relation of essential-fatty acid and methionine deficiencies to hypercholesteræmia may help to clarify some of the observations of Best et al.[6] and of Stare et al[7] on the atherogenic effects of deficiency of choline, of methionine and of cystine

If one accepts as a working hypothesis the concept that transport of fatty acid is the major function of cholesterol[8] and recalls that the "normal" fatty acid, which is esterified with cholesterol, is an unsaturated acid,[8] it would seem not improbable that relative or absolute unavailability of essential fatty acids may result in "jamming" of cholesterol metabolism, with resultant increase in production and abnormal deposition of cholesterol If this concept be even partly correct, it is obvious that experimental efforts designed to evaluate the specific metabolic functions of essential fatty acids per se, are important Such studies are under way in this laboratory

Dr Keys (April 28) is less than enthusiastic regarding the concept of the importance of essential-fatty-acid deficiency in the pathogenesis of atheromatosis Dr Keys says "We have observed this [i e, differential effects of different fats upon cholesterogenesis] as well as others, including Kinsell in California, Ahrens in New York and, recently, Bronte Stewart in South Africa" Dr Keys until recently felt that fats were fats, and all were equally bad in regard to cholesterogenesis Since he appears to have accepted the weight of evidence for the profound differences in "cholesterogenic effects" between some animal and vegetable fats, we may expect that before too long he will decide that deficiency of essential fatty acids plays an important role in the pathogenesis of degenerative vascular disease

Institute for Metabolic Research
Highland Alameda County
Hospital Oakland 6 California LAURANCE W KINSELL

SIR,—May I add my humble voice to the recent flurry of interest engendered by Dr Sinclair's letter on the possible multitudinous rôles of essential fatty acids in disease? Perhaps this series of letters should be entitled "Hard Fats and Hard Arteries"! Although we are living in an age of rapid advances and as rapidly crystallising opinions, the healthy controversy let loose may well mark the initial break-through in one aspect of the problem of atherosclerosis While I may be accused of speaking upon a subject to which I am a relative newcomer, my attention in the past three years has been devoted to orienting myself through the slough of fats, lipoprotein carriers (alpha and beta), S_f and S-negative particles, Cohn fractions, phospholipids, lipid phosphorus, free and esterified fractions of cholesterol and their ratios, neutral fats and triglycerides, choline and methionine effects and the relative incidences of arterial diseases in countries torn by war and altered by peace The purpose of this attempt at orientation was to find what approaches might lead to therapy, for our formerly hypertensive patients are no longer dying of their disease but of atherosclerosis and its manifestations

Out of these contemplations came a regression (because of confusion) to non-ultracentrifugal simples and to Aschoff's statement 'From plasma of low cholesterol content no deposition of lipoids will occur even though the mechanical conditions are favourable"[9] Added to this might be "It may matter little how cholesterol and its esters are carried in blood, what is important is the blood level and the nature of the ester" Schonheimer's old but careful analyses of aortic plaques showed clearly that esters of cholesterol increased with severity of the lesions[10], several fatty acids were demonstrated, but the principal ones were saturated or monoethenoid (stearate, palmitate, oleate) The solubilities of cholesterol esters of unsaturated fatty acids are greater than are those of saturated acids with chains of equal lengths[11]

To my knowledge, Snapper was the first to suggest that deficiency of unsaturated acids might lead to atherosclerosis,[12] by pointing out the low incidence of the

cases discussed above Furthermore, spontaneous movements, though sometimes few, were never entirely absent Of the children with cerebral palsy 4 had a history of possible birth injury, and as they grew older, abnormal postures, stiffness and clumsiness of the limbs, or involuntary movements appeared, while there was no muscular wasting, in these cases, too, the tendon reflexes were present throughout and sometimes exaggerated In the mentally defective children it gradually became apparent that their delay in physical development was accompanied by a parallel deficit in emotional and intellectual attainments The diagnosis of mental defect in infancy is never easy, but in these children the true state of affairs was generally apparent by the end of the first year of life In the cases of scurvy, arachnodactyly, and the other conditions listed above, it also became clear with the passage of time that the moderate degree of muscular weakness and hypotonia shown by the patient was not due to a primary neuromuscular disorder The same will usually be true in cases of malnutrition or in endocrine or metabolic disorders, usually signs of the primary disease, of which the hypotonia is but a symptom, will be evident In glycogen-storage disease, for instance, hepatic enlargement will often be found Furthermore, in patients with hypermobile joints due to congenital laxity of the ligaments there is no impairment of spontaneous movements or of muscular development, and often the condition affects more than one member of the family

It is thus apparent that, in most cases diagnosed as amyotonia congenita, the nature of the underlying disease will be revealed as a result of repeated clinical observations, particularly during the first year of life Cases of spinal muscular atrophy will deteriorate during this time, unlike benign congenital hypotonia, while in brain-injured or mentally defective children signs of the central nervous disorder, or a failure of intellectual development, may come to light It is natural that an anxious parent will press for an answer at a first interview, but it is surely far wiser to temporise in any case of doubt than to give a gloomy prognosis which may not be justified by subsequent events If doubt persists, as it may, after two or three interviews, it will often be necessary to admit the patient to hospital for observation and for investigations, including electromyography and muscle biopsy, which, if done with care, will always either confirm or refute a diagnosis of spinal muscular atrophy If these studies and metabolic investigations are normal, it may still be necessary to await the appearance of involuntary movements—e g, in cases of cerebral palsy—or signs of spontaneous improvement (suggesting a diagnosis of benign hypotonia) before making a final diagnosis

The findings in this series of cases have led to the conclusion that the term " amyotonia congenita " should be discarded, unless it is used with the clear understanding that it refers to the syndrome of infantile hypotonia and is not taken to designate a specific disease It is surely more satisfactory to call all cases of spinal atrophy, whether beginning at birth or subsequently, " infantile spinal muscular atrophy " or " Werdnig Hoffmann disease " " Amyotonia congenita " should not be used to denote such cases, because in the minds of many physicians this diagnosis raises the possibility of spontaneous improvement Furthermore, although the cases of " benign congenital hypotonia " referred to in this paper correspond most closely to Oppenheim's original description of amyotonia, it is preferable that these too should be identified by a new descriptive term such as the one given, in view of the many varied meanings which have become attached to " amyotonia " over the years Clearly, all hypotonic babies require meticulous observation until the nature of the disease responsible for the muscular manifestations becomes apparent, only then may it be possible to offer an accurate prognosis

Summary

The results are reported of a follow-up study of 109 cases which had been diagnosed as amyotonia congenita, usually in infancy, 2–25 years before

In 67 patients the disease giving rise to generalised hypotonia and hypermobility had been progressive, and 55 of them had died between the ages of 5 weeks and 12 years The 12 survivors were severely disabled and were aged 4–20 years at the time of follow up In these 67 cases the disease was clearly spinal muscular atrophy, whether the condition was present at birth or began late in the first year of life made little difference to the subsequent history of the illness

Of the remaining 42 patients, 8 had recovered completely 9 other patients had improved considerably but had remained moderately disabled throughout life, with general weakness and decrease in bulk of the skeletal musculature, the condition of these patients corresponded to descriptions of " benign congenital myopathy," but reasons are given for supposing that they did not have a true muscular dystrophy It is suggested that the entire syndrome, embracing the cases which recover completely and those in which recovery is incomplete, may reasonably be called " benign congenital hypotonia " The two forms of this syndrome may be the different end-results of a similar neuromuscular abnormality present at birth, in some cases the condition may be entirely overcome by the processes of postnatal development, but in others some muscular disability persists Another 5 patients were found to have muscle disease, 1 had a picture like that of benign congenital hypotonia but with myasthenic features, 3 eventually showed the characteristic features of progressive muscular dystrophy, and 1 was a case of polymyositis (chronic myositis fibrosa)

6 other patients were found on follow-up to have some form of " cerebral palsy," and 8 others were mentally defective and showed no sign of neuromuscular disease In the remaining 6 cases it was apparent that the muscular hypotonia observed in infancy had been due to scurvy (2 cases), arachnodactyly, multiple congenital defects, congenital dislocation of the hip, and spinal ganglioneuroma

The differential diagnosis of the many conditions which may give rise to the syndrome of amyotonia congenita (the limp floppy baby) is discussed Many clinical observations at intervals may be required before the underlying disease can be accurately diagnosed In difficult cases investigations such as muscle biopsy may be helpful The term " *amyotonia congenita* " should be discarded, unless it is taken to mean the clinical syndrome of infantile hypotonia without any prognostic implications Spinal atrophy should be called " infantile spinal muscular atrophy " or " Werdnig-Hoffmann disease," whatever the age of onset, and the name " amyotonia congenita " should not be used to denote cases of this type

I wish to thank the physicians and surgeons of the National Hospital and of the Hospital for Sick Children for permission to consult their records and to follow up their cases, Dr E A Carmichael and Prof A A Moncrieff for encouragement and advice, the medical committee of the National Hospital and the research committee of the Hospital for Sick Children for their support, Dr B Kiernander and the staff of the department of physical medicine in the Hospital for Sick Children for making available many of the facilities necessary for this work, Miss M Mayfield, the almoner, for assistance in tracing some of the cases, and Mrs B Wilson for valuable assistance in this survey

vertebra Within a few minutes paraplegia developed with sensory loss up to T6 segment Lumbar puncture was carried out and a clear fluid smelling strongly of phenol was obtained Chemical tests confirmed the presence of phenol The paraplegia wore off in three hours, but the patient had weakness of the quadriceps femoris on the side of injection which took three months to disappear

It would seem that the needle must have entered an intervertebral foramen and pierced the dura, although no cerebrospinal fluid dripped from it and test aspirations were negative The weakness of the quadriceps is explained by the high concentration of the phenol round the spinal nerve roots emerging at the site of injection

This case has been the only one with neurological complications out of several hundred treated personally by such injections, and it certainly emphasises the need for great care when carrying out paravertebral injections of potent fluids In addition, it indicates that a considerable amount of phenol can be introduced intrathecally without lasting damage to the spinal cord In the light of this evidence it seems most unlikely that an ampoule of spinal-anæsthetic fluid immersed in 5% phenol solution could absorb, through microscopic cracks, enough phenol to cause a permanent paraplegia when injected intrathecally As Sir Francis Walshe indicates (June 2), the only common factor in the reported cases of paraplegia after spinal anæsthesia is the use of a spinal anæsthetic, and it seems clear that the risk of such a tragic complication is inherent in the injection, no matter how perfect the technique of its administration

CAUSE OF HYPOGLYCÆMIC SYMPTOMS

SIR,—In your interesting annotation of June 9 you state that it is hard to estimate the significance of our finding that sweating still occurs in response to hypoglycæmia in patients after thoracolumbar sympathectomy It should be made clear that sweating was only seen in the regions, such as the face and upper limbs, not affected by the sympathectomy No sweating was seen in the regions denervated by the operation However, the point at issue is whether sweating still occurs when, owing to adrenal denervation, adrenaline is not liberated The persistence of sweating in these patients is thus further evidence that adrenaline plays no part in sweating due to hypoglycæmia

The lack of correlation between adrenaline release and occurrence of sweating is demonstrated in several other observations You mention the fact that intravenous infusions of adrenaline do not produce sweating It is also of interest that the sweating which is a conspicuous feature in a patient with a phæochromocytoma may persist for several days after removal of the tumour,[1] and clearly it cannot be due primarily to the excessive liberation of adrenaline

BUTALITHONE SODIUM IN ELECTROCONVULSIVE THERAPY

SIR,—It may be of interest to mention our preliminary experience with butalithone sodium ('Transithal,' 'Ulbreval') as a substitute for thiopentone sodium in anæsthesia for electroconvulsive therapy

We have found that butalithone sodium, in a dose of 0 25–0 5 g given intravenously over half a minute, depresses respiration less than does thiopentone, so that usually inflation is unnecessary The patient speedily returns to a safe state of consciousness, so that a junior nurse may be left in charge and the interval before full recovery is very considerably shorter, so that less time is wasted in waiting both by patients and staff in a busy outpatient department

In our experience, extending over several hundred cases, side effects, such as hiccup and retching, have been no commoner than with thiopentone

APPENDICECTOMY DURING GYNÆCOLOGICAL OPERATIONS

SIR,—British gynæcologists have always been somewhat doubtful about the advisability of routine appendicectomy when performing hysterectomy or other abdominal gynæcological operations Some British surgeons, however, and many Americans[1] include appendicectomy as a routine The late Victor Bonney always advised against routine appendicectomy, and obedience to the principles of this great master has caused me regret on only 3 occasions in which acute appendicitis followed within one week of hysterectomy, involving the patient in a further emergency operation I have seen a similar complication twice after vaginal hysterectomy In 1 of these patients a gangrenous appendix with peritonitis was removed forty eight hours after operation, and in another a chronic pelvic abscess involving the right fallopian tube and ovary developed and was operated upon three months after the original procedure

The great argument against routine appendicectomy has been the danger of disseminating infection from the bowel wound in the cæcum into the recently exposed cellular planes of the retroperitoneal space It is certainly true that the pelvic peritoneum recently traumatised by the operation of hysterectomy has not the same ability to resist infection as when the pelvis is intact It is possible, too, that the pelvic peritoneum is already *fully* occupied in dealing with the contamination from the vagina inherent in total hysterectomy and that the two portals of *infection* may, in certain instances, prove overwhelming

Although it is interesting to speculate on these possible sources of infection, I felt that, if exact information could be obtained from a representative number of British gynæcological surgeons, the results might be helpful to those who, like myself, wonder what is the best and safest procedure A questionnaire was, therefore addressed to 31 surgeons, and their replies are summarised below

(1) Do you remove the appendix as a routine when per*forming hysterectomy ?*

No 26, *Yes* 5

(2) Have you seen any complications as a result of this operation, such as peritonitis, intestinal obstruction, &c ?

No 25, *Yes* 6 (burst abdomen 1, peritonitis 7, intestinal obstruction 1, *Escherichia coli* infection of wound 6) (Of the 6 replying "yes," some had seen more than 1 complication—hence the discrepancy in the figures)

(3) Have you encountered any complications from not removing the appendix ?

No 30, *Yes* 1 (a case of appendicectomy after myomectomy followed by fatal peritonitis)

Of these "noes," 7 recalled patients in whom appendicectomy was necessary within a few months of the hysterectomy There is no evidence to connect the hysterectomy directly with the appendicitis—i e it did not occur within one month of the operation, as in my cases

(4) Can you give me any *references to any* published work on this subject ?

The replies to this question were an almost universal blank apart from the figures published by the Royal Society of Medicine in 1949 from the Samaritan Hospital London

(5) Any other observations ?

Of the 26 surgeons who do not routinely remove the appendix, 16 made the observation that they would

IDIOPATHIC HYPERCALCÆMIA OF INFANTS

K RHANEY
M B Edin , M R C P E
SENIOR LECTURER IN CHILD HEALTH
IN THE UNIVERSITY OF ST ANDREWS

R G MITCHELL
M D Edin , M R C P E , D C H
CONSULTANT PÆDIATRICIAN,
ROYAL INFIRMARY AND MARYFIELD HOSPITAL, DUNDEE

IDIOPATHIC hypercalcæmia of infants is of two types (Lightwood and Stapleton 1953 Lowe et al 1954) benign or simple, with a good prognosis , and severe, with a bad prognosis and associated with mental retardation, a peculiar facial appearance, and osteosclerosis In both types calcium metabolism is deranged apparently exactly as in vitamin D intoxication (Creery and Neill 1954, Bonham Carter et al 1955)

Four infants with so called benign hypercalcæmia died in Dundee Three studied at necropsy are reported here , all had gross nephrocalcinosis and one had metastatic arterial calcification in the brain The clinical features and pathology were compared with those of other diseases causing renal calcification In particular, through the kindness of Dr Agnes R Macgregor, we have studied sections from the two cases of renal calcification which she described in the papers by Thatcher (1931, 1936) on hypervitaminosis D

Case-reports

FIRST CASE

A girl, born spontaneously on May 6, 1955 (birth weight 6 lb 2 oz), made good progress until the age of 6 months, when she weighed 17 lb 4 oz About then she suddenly became limp and pale for about 15 minutes but recovered rapidly She had similar attacks at the ages of 8 and $8^1/_2$ months She developed anorexia and constipation, began to lose weight, and vomited occasionally At the age of 9 months she was admitted to hospital on Feb 8, 1956 She had been fed on National dried milk from the age of 2 weeks and on admission she was receiving 30 oz of full cream National dried milk and about $1^1/_2$ oz of 'Farex' daily She was given half a teaspoonful of cod liver oil compound (400 I U of vitamin D) occasionally and a teaspoonful of 'Milk of Magnesia' every second day Her parents and a sister were healthy

On admission she was alert and of normal facial appearance weighed 16 lb 14 oz , was not dehydrated, and had no muscular hypotonia No cardiac murmur was heard, and an electrocardiogram was normal , her blood pressure was 120/70 mm Hg Radiography of her chest, abdomen, long bones, and skull showed no abnormality Three estimations of the plasma calcium level gave values of 12 7, 12 2, and 14 5 mg per 100 ml The blood urea level was 48 mg per 100 ml , plasma phosphate level 4 5 mg per 100 ml , plasma chloride level 98 m eq per litre, plasma bicarbonate level 20 1 m eq per litre, plasma cholesterol level 375 mg per 100 ml plasma albumin level 4 8 g per 100 ml plasma globulin level 1 7 g per 100 ml , plasma alkaline phosphatase level 16 3 King Armstrong units, hæmoglobin 12 4 g per 100 ml and leucocyte count 20 500 per c mm A catheter specimen of urine (pH 4) contained a trace of protein and a few leucocytes and was sterile on culture

Treatment and Course

The baby was treated with 'Locasol' (Trufood)—a dried milk low in calcium content—and oxytetracycline 250 mg daily by mouth , the leucocytes disappeared from the urine, and she gained weight despite anorexia and occasional vomiting *On Feb 28 she began to vomit more frequently and* passed a loose stool from which no pathogenic organisms were isolated Dehydration developed and was corrected with intravenous fluid Oxytetracycline was added to the infusion but despite this irregular pyrexia developed On March 3 the plasma calcium level was 11 4 mg per 100 ml , plasma phosphate level 3 6 mg per 100 ml , plasma alkaline phosphatase level 12 King Armstrong units, blood urea level 17 mg per 100 ml , plasma sodium level 139 m eq per litre, plasma potassium level 4 2 m eq per litre, and plasma chloride level 89 m eq per litre Intravenous therapy was discontinued, and locasol was given but was vomited , several loose stools were passed, but again no pathogenic bacteria were isolated At this stage the administration of cortisone 25 mg six hourly, potassium chloride, and locasol by intragastric drip improved her condition and stopped the vomiting Because the pyrexia continued, chloramphenicol was substituted for oxytetracycline On March 5, however, vomiting recurred, and the infant again became dehydrated An intravenous drip was started, but her condition deteriorated and she died next day, at the age of 10 months

Necropsy Findings

The body was that of a dehydrated infant weighing 14 lb 6 oz The *kidneys* were of average size (rt 25 g , lt 21 g) firm, and pale The capsule was healthy and the cortical surface smooth On section there were numerous foci of calcification in the outer medulla, forming radial white streaks, 1–2 mm long, parallel with the line of the tubules No deposits were seen in the apical half of the pyramids or in the cortex The *ribs* showed sclerosis of the cortex near the costochondral junctions Skull, lumbar vertebræ, femur, skeletal muscles, cardiovascular system (heart 30 g), respiratory, alimentary, endocrine lymphatic, hæmopoietic systems and central nervous system (brain 925 g) appeared normal

Histology

The appearance of the kidneys is described in detail below *Ribs* the cortex was much thickened but the trabeculæ were less affected The bony architecture was normal There was severe focal calcification of the media of a branch of the *middle cerebral artery* within the basal ganglia No pathological changes were found in the brain and spinal cord *Heart* a minute thrombus on the posterior wall of the left atrium was undergoing organisation , no calcification was seen *Liver* showed slight centrilobular atrophy *Œsophagus* showed slight ulceration immediately above the cardia Three *parathyroid glands* were found, of normal size and appearance Lungs tongue, submandibular salivary gland stomach and intestines, pituitary, thyroid, and adrenal glands pancreas, spleen, thymus muscles, skin internal genital organs ureters and bladder, arteries vertebræ and femur appeared normal

SECOND CASE

A report of this boy's illness has already been published (Morgan et al 1956 case 2) He was admitted on Sept 2 1954, at the age of 8 months because of anorexia, vomiting, and constipation

On admission his facial appearance was normal and no cardiac murmur was heard His plasma calcium level was 14 8 *mg per 100 ml* blood urea level 50 mg per 100 ml plasma bicarbonate level 23 3 m eq per litre and plasma chloride level 97 4 m eq per litre His urine (pH 7 5) contained

remove it if, on inspection, they found it to be diseased, to look unhealthy, to be kinked, to be adherent retrocæcally, or to contain fæcoliths A few commented that appendicectomy undoubtedly increased the risk of postoperative pyrexia and infection and that it was a complicating factor in the convalescence after hysterectomy

As a result, the following suggestions can be made

(1) That British gynæcologists, by a majority, do not advise routine appendicectomy when performing hysterectomy

(2) That this rule should not be followed unreasonably and the appendix, if obviously diseased or unhealthy, or if containing fæcoliths, is probably best removed

(3) That there is a real danger of local and general peritonitis, and that simultaneous appendicectomy and hysterectomy should be covered by a course of postoperative antibiotics

I acknowledge the kind coöperation of the members of the Gynæcological Travellers' Club and other colleagues who kindly answered my questionnaire

FATS AND DISEASE

SIR,—Dr Sinclair's letter (April 7) intrigues me

In 1952 and subsequently we reported studies, begun in 1950, which showed a profound decrease in plasma cholesterol and phospholipids, in patients maintained on diets containing large amounts of unsaturated vegetable fats[1 2] Among the possible reasons for such an effect were considered (1) absence of cholesterol, per se, (2) a positive effect of some vegetable sterol, (3) a positive effect of vegetable phospholipid, (4) a positive effect of one or more fatty acids present in the vegetable fat

Over the intervening years, by a process of exclusion, all except the last have been essentially eliminated Studies in which fats of vegetable origin, but of very different iodine number, have been alternated in the diet have shown that the decrease in plasma cholesterol and phospholipid levels is directly related to the amount of unsaturated fat present in the diet[3] A very recent study, in which 100 g of a synthetic triglyceride, containing approximately 2 g of linoleic acid, has been administered daily,[4] further implements this conclusion

Dr Sinclair's observations regarding abnormal deposition of lipids in the skin under conditions of essential-fatty acid deficiency are of considerable interest, as are his speculations regarding the very possible rôle of essential fatty acid and/or pyridoxine deficiency in the pathogenesis of degenerative vascular disease His observations regarding increased requirement for essential fatty acid in male animals may be particularly pertinent in this regard

The work of Shapiro and Freedman[5] on the relation of essential fatty acid and methionine deficiencies to hypercholesteræmia may help to clarify some of the observations of Best et al[6] and of Stare et al[7] on the atherogenic effects of deficiency of choline, of methionine, and of cystine

If one accepts as a working hypothesis the concept that transport of fatty acid is the major function of cholesterol[4] and recalls that the "normal" fatty acid, which is esterified with cholesterol, is an unsaturated acid,[8] it would seem not improbable that relative or absolute unavailability of essential fatty acids may result in "jamming" of cholesterol metabolism, with resultant increase in production and abnormal deposition of cholesterol If this concept be even partly correct, it is obvious that experimental efforts designed to evaluate the specific metabolic functions of essential fatty acids, per se, are important Such studies are under way in this laboratory

Dr Keys (April 28) is less than enthusiastic regarding the concept of the importance of essential-fatty-acid deficiency in the pathogenesis of atheromatosis Dr Keys says "We have observed this [i e, differential effects of different fats upon cholesterogenesis] as well as others, including Kinsell in California, Ahrens in New York, and, recently, Bronte Stewart in South Africa" Dr Keys until recently felt that fats were fats and all were equally bad in regard to cholesterogenesis Since he appears to have accepted the weight of evidence for the profound differences in "cholesterogenic effects" between some animal and vegetable fats, we may expect that before too long he will decide that deficiency of essential fatty acids plays an important role in the pathogenesis of degenerative vascular disease

Institute for Metabolic Research
Highland Alameda County
Hospital Oakland 6 California   LAURANCE W KINSELL

SIR,—May I add my humble voice to the recent flurry of interest engendered by Dr Sinclair's letter on the possible multitudinous rôles of essential fatty acids in disease? Perhaps this series of letters should be entitled "Hard Fats and Hard Arteries"! Although we are living in an age of rapid advances and as rapidly crystallising opinions the healthy controversy let loose may well mark the initial break-through in one aspect of the problem of atherosclerosis While I may be accused of speaking upon a subject to which I am a relative newcomer my attention in the past three years has been devoted to orienting myself through the slough of fats, lipoprotein carriers (alpha and beta), S_f and *S-negative particles, Cohn fractions, phospholipids, lipid* phosphorus, free and esterified fractions of cholesterol and their ratios, neutral fats and triglycerides, choline and methionine effects, and the relative incidences of arterial diseases in countries torn by war and altered by peace The purpose of this attempt at orientation was to find what approaches might lead to therapy, for our formerly hypertensive patients are no longer dying of their disease but of atherosclerosis and its manifestations

Out of these contemplations came a regression (because of confusion) to non ultracentrifugal samples and to Aschoff's statement "From plasma of low cholesterol content no deposition of lipoids will occur even though the mechanical conditions are favourable"[9] Added to this might be "It may matter little how cholesterol and its esters are carried in blood, what is important is the blood level and the nature of the ester" Schönheimer's old but careful analyses of aortic plaques showed clearly that esters of cholesterol increased with severity of the lesions[10], several fatty acids were demonstrated, but the principal ones were saturated or monoethenoid (stearate, palmitate, oleate) The solubilities of cholesterol esters of unsaturated fatty acids are greater than are those of saturated acids with chains of equal lengths[11]

To my knowledge, Snapper was the first to suggest that deficiency of unsaturated acids might lead to atherosclerosis,[12] by pointing out the low incidence of the

a few pus cells but no protein Radiographs of his skull and long bones were normal

Treatment and Course

His condition improved on treatment with cortisone and a low calcium diet, but on Dec 29, 1954, diarrhœa and vomiting developed, his urine contained protein and pus, and culture of a mid stream specimen yielded a growth of proteus No pathogenic organisms were grown from his stools He became dehydrated and was given intravenous fluid and intramuscular streptomycin 300 mg daily On Dec 31, 1954, he had a small hæmatemesis, and his plasma calcium level was 10 1 mg per 100 ml, plasma phosphorus level 6 4 mg per 100 ml, and blood urea level 95 mg per 100 ml By next day his condition had improved, and further improvement followed blood transfusion In spite of this improvement, however, he continued to vomit a little, and during the night of Jan 3, 1955, he became restless, had another small hæmatemesis, and died in coma within an hour (age 1 year)

Necropsy Findings

The body was that of an ill nourished infant weighing 13 lb The right leg was slightly œdematous proximal to the site of an intravenous drip (permission to examine the leg veins was withheld) The *kidneys* (rt 26 g, lt 31 g) were like those of case 1 (see below), but contained even greater deposits of calcium in the outer medulla, chiefly in the boundary zone *Ureters* and *bladder* were normal The *heart* weighed 35 g Many branches of the *pulmonary arteries* within the lungs were almost occluded by old and recent thrombus Both *lungs* were congested and contained small foci of early infarction at the bases The *œsophagus* contained a little blood apparently derived from superficial erosions immediately proximal to the cardia The *liver* (215 g) had a nutmeg appearance Examination of the central nervous system was not permitted Skeletal and muscular systems and endocrine, lymphatic, and hæmopoietic systems appeared normal

Histology

Kidneys see below *Lungs* showed early bronchopneumonia hæmorrhage, and small foci of early infarction The thrombus in the pulmonary arteries was undergoing organisation, and some was almost superseded by fibrous tissue *Liver* showed severe fatty change *Œsophagus* showed superficial ulceration and inflammation Two *parathyroid glands* were found, both were normal Arteries, stomach and intestines, thyroid pancreas, adrenals, muscles ribs vertebræ, thymus. and spleen appeared normal

THIRD CASE

A girl, born spontaneously on Dec 2 1954 (birth-weight 8 lb 9 oz), progressed satisfactorily until the age of 6 months, when she weighed *15 lb 5 oz*, but thereafter she became pale and listless and began to refuse her feeds Once she appeared to inhale some milk and a slight cough developed There was no vomiting but anorexia and listlessness persisted, and she was admitted at the age of 7½ months on July 23, 1955 She had been breast fed for a week after birth but thereafter given National dried milk Half a teaspoonful of cod liver oil compound (400 I U of vitamin D) was given daily from the age of 3 weeks, cereal foods were introduced at the age of 4 months She was given fluid magnesia or milk of magnesia almost every night Her parents and two brothers were healthy

On admission she was pale, flabby, and of normal facial appearance, and smiled readily She weighed only 13 lb 3 oz but was not dehydrated No cardiac murmur was heard Radiographs of her chest and long bones were normal Her plasma calcium level was 16 3 mg per 100 ml blood urea level 63 mg per 100 ml, plasma sodium level 150 m eq per litre, plasma chloride level 103 m eq per litre, and plasma bicarbonate level 17 m eq per litre, Hb 11 9 g per 100 ml, and leucocyte count 20,500 per c mm Her urine was acid (pH not recorded) and contained no protein, a catheter specimen showed 1–2 leucocytes per high power field, and *Escherichia coli* was isolated on culture

Treatment and Course

Sulphadimidine 0 25 g four hourly was given for four days, the high level of plasma calcium then became known, and intramuscular streptomycin 150 mg twice daily was substituted On this day the baby's temperature rose to 100 4°F and she vomited several times By next day (Aug 1, 1955) she was dehydrated although she had no diarrhœa, and her temperature had risen to 104 6°F, she then had a slight convulsion Her urine contained only a few leucocytes and was sterile on culture Intravenous fluid containing oxytetracycline was given, and by next morning her temperature had fallen to 99°F and she was less dehydrated Her plasma calcium level was now 9 6 mg per 100 ml, blood urea level 70 mg per 100 ml, plasma sodium level 139 m eq per litre, plasma potassium level 3 1 m eq per litre, plasma chloride level 109 m eq per litre, plasma bicarbonate level 18 m eq per litre, plasma phosphorus level 3 3 mg per 100 ml, plasma albumin level 3 3 g per 100 ml, plasma globulin level 2 2 g per 100 ml, and plasma alkaline phosphatase level 10 King-Armstrong units Her Hb was only 11 0 g per 100 ml, so a blood transfusion of 85 ml was given Throughout this day she improved she began to take interest in her surroundings and drank some milk, but she still vomited occasionally The intravenous drip was stopped and oxytetracycline continued by mouth She relapsed for no apparent reason during the following forty eight hours and died in coma on Aug 5, 1955, at the age of 8 months

Necropsy Findings

The body was that of a dehydrated female infant weighing 12 lb 14 oz The *kidneys* (rt 42 g, lt 30 g) were like those of cases 1 and 2, the only feature of note was the presence of heavy deposits of calcium confined to the outer medulla Ureters bladder, and internal *genitalia* were healthy Both *pleural sacs* contained a slight excess of serous fluid, and the *right lung* showed partial collapse posteriorly *Œsophagus*, *stomach*, and *intestines* contained a little blood apparently derived from superficial ulceration of the œsophagus immediately proximal to the cardia The cardiovascular system (heart 34 g), endocrine, skeletal and muscular systems, lymphatic and hæmopoietic systems, and central nervous system appeared normal

Histology

Kidneys see below *Lungs* showed slight chronic interstitial inflammation possibly resulting from aspiration *Œsophagus* was ulcerated and inflamed at the cardiac end Many nerve-cells in the *basal ganglia* and the Purkinje cells of the *cerebellum* showed terminal ischæmia One *parathyroid gland* was found it was histologically normal Heart and arteries, tongue, stomach, intestine, liver, thyroid, pancreas, adrenal glands, muscles, skin, internal genital organs, ureter, bladder, rib, ilium and vertebræ appeared normal

HISTOLOGY OF KIDNEYS

Case 1

Calcification was not confined to the medulla, but the few deposits in the cortex were extremely small Nearly all the medullary calcium was present in a granular amorphous form within foci of degeneration These foci were of different sizes and shapes Their numerical and anatomical distribution at different levels of the medulla suggested that they had developed in relation to the loops of Henle Thus, most of them were situated in the outer half of the medulla, where about seven eighths of the loops of Henle are said to turn back towards the cortex (Maximow and Bloom 1948), they were more sparse in the middle of the medulla and there occupied the position of the loops of Henle adjacent to and encircling the collecting tubules (fig 1), and the few foci in the apical region of the pyramids were surrounded by collecting tubules

Calcium had been deposited in the foci both in a finely granular form and in a coarser form The deposits contained abundant alkaline phosphatase and showed disintegration of the supporting stroma and basement membranes, and necrosis of the epithelium of adjacent tubules This latter change involved particularly those tubules in the position of loops of Henle and could be followed by their complete disappearance (fig 1, cf fig 6) The collecting tubules also showed segmental disintegration, although generally these tubules were less severely injured, involvement of their basement membrane and epithelium was occasionally followed by narrowing of the lumen, but most of the collecting tubules within these zones of disintegrating tissue were distinctly dilated

vertebra Within a few minutes paraplegia developed with sensory loss up to T6 segment Lumbar puncture was carried out and a clear fluid smelling strongly of phenol was obtained Chemical tests confirmed the presence of phenol The paraplegia wore off in three hours, but the patient had weakness of the quadriceps femoris on the side of injection which took three months to disappear

It would seem that the needle must have entered an intervertebral foramen and pierced the dura, although no cerebrospinal fluid dripped from it and test aspirations were negative The weakness of the quadriceps is explained by the high concentration of the phenol round the spinal nerve-roots emerging at the site of injection

This case has been the only one with neurological complications out of several hundred treated personally by such injections, and it certainly emphasises the need for great care when carrying out paravertebral injections of potent fluids In addition, it indicates that a considerable amount of phenol can be introduced intrathecally without lasting damage to the spinal cord In the light of this evidence it seems most unlikely that an ampoule of spinal-anæsthetic fluid immersed in 5% phenol solution could absorb, through microscopic cracks, enough phenol to cause a permanent paraplegia when injected intrathecally As Sir Francis Walshe indicates (June 2), the only common factor in the reported cases of paraplegia after spinal anæsthesia is the use of a spinal anæsthetic, and it seems clear that the risk of such a tragic complication is inherent in the injection, no matter how perfect the technique of its administration

Manchester HERBERT HAXTON

CAUSE OF HYPOGLYCÆMIC SYMPTOMS

SIR,—In your interesting annotation of June 9 you state that it is hard to estimate the significance of our finding that sweating still occurs in response to hypoglycæmia in patients after thoracolumbar sympathectomy It should be made clear that sweating was only seen in the regions such as the face and upper limbs, not affected by the sympathectomy No sweating was seen in the regions denervated by the operation However, the point at issue is whether sweating still occurs when, owing to adrenal denervation, adrenaline is not liberated The persistence of sweating in these patients is thus further evidence that adrenaline plays no part in sweating due to hypoglycæmia

The lack of correlation between adrenaline release and occurrence of sweating is demonstrated in several other observations You mention the fact that intravenous infusions of adrenaline do not produce sweating It is also of interest that the sweating which is a conspicuous feature in a patient with a phæochromocytoma may persist for several days after removal of the tumour,[1] and clearly it cannot be due primarily to the excessive liberation of adrenaline

BUTALITHONE SODIUM IN ELECTROCONVULSIVE THERAPY

SIR,—It may be of interest to mention our preliminary experience with butalithone sodium ('Transithal,' 'Ulbreval') as a substitute for thiopentone sodium in anæsthesia for electroconvulsive therapy

We have found that butalithone sodium, in a dose of 0 25–0 5 g given intravenously over half a minute, depresses respiration less than does thiopentone, so that usually inflation is unnecessary The patient speedily returns to a safe state of consciousness, so that a junior nurse may be left in charge, and the interval before full recovery is very considerably shorter, so that less time is wasted in waiting both by patients and staff in a busy outpatient department

In our experience, extending over several hundred cases, side effects, such as hiccup and retching, have been no commoner than with thiopentone

APPENDICECTOMY DURING GYNÆCOLOGICAL OPERATIONS

SIR,—British gynæcologists have always been somewhat doubtful about the advisability of routine appendicectomy when performing hysterectomy or other abdominal gynæcological operations Some British surgeons, however, and many Americans[1] include appendicectomy as a routine The late Victor Bonney always advised against routine appendicectomy, and obedience to the principles of this great master has caused me regret on only 3 occasions in which acute appendicitis followed within one week of hysterectomy, involving the patient in a further emergency operation I have seen a similar complication twice after vaginal hysterectomy In 1 of these patients a gangrenous appendix with peritonitis was removed forty-eight hours after operation, and in another a chronic pelvic abscess involving the right fallopian tube and ovary developed and was operated upon three months after the original procedure

The great argument against routine appendicectomy has been the danger of disseminating infection from the bowel wound in the cæcum into the recently exposed cellular planes of the retroperitoneal space It is certainly true that the pelvic peritoneum recently traumatised by the operation of hysterectomy has not the same ability to resist infection as when the pelvis is intact It is possible, too, that the pelvic peritoneum is already fully occupied in dealing with the contamination from the vagina inherent in total hysterectomy and that the two portals of infection may, in certain instances, prove overwhelming

Although it is interesting to speculate on these possible sources of infection, I felt that, if exact information could be obtained from a representative number of British gynæcological surgeons, the results might be helpful to those who, like myself, wonder what is the best and safest procedure A questionnaire was, therefore addressed to 31 surgeons, and their replies are summarised below

(1) *Do you remove the appendix as a routine when performing hysterectomy ?*
No 26, *Yes* 5

(2) Have you seen any complications as a result of this operation, such as peritonitis, intestinal obstruction &c ?
No 25, *Yes* 6 (burst abdomen 1, peritonitis 7, intestinal obstruction 1, *Escherichia coli* infection of wound 6) (Of the 6 replying 'yes," some had seen more than 1 complication—hence the discrepancy in the figures)

(3) Have you encountered any *complications from not* removing the appendix ?
No 30, *Yes* 1 (a case of appendicectomy after myomectomy followed by fatal peritonitis)

Of these 'noes," 7 recalled patients in whom appendicectomy was necessary within a few months of the hysterectomy There is no evidence to connect the hysterectomy directly with the appendicitis—i e it did not occur within one month of the operation, as in my cases

(4) Can you give me any *references to any* published work on this subject ?

The replies to this question were an almost universal blank, apart from the figures published by the Royal Society of Medicine in 1949 from the Samaritan Hospital London

(5) Any other observations ?

Of the 26 surgeons who do not routinely remove the appendix, 16 made the observation that they would

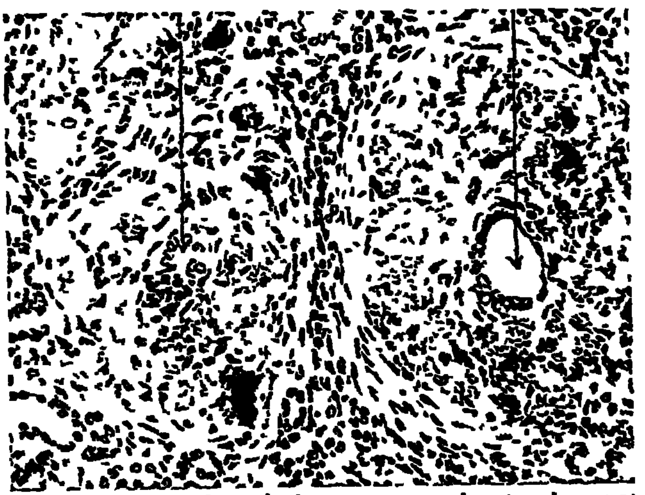

Fig. 1—Renal tissue of case 1, showing two granulomatous lesions at sites of amorphous deposits encircling damaged collecting tubules (arrowed). The histiocytic reaction is accompanied by giant cells, and fibrosis has developed at the periphery of each lesion. (Hæmatoxylin and eosin. × 220.)

These foci were infiltrated by histiocytic cells with twisted pyknotic nuclei; a few multinucleated giant cells were also present (fig. 1), but these were not all of foreign-body type, some apparently being shrivelled degenerating tubular epithelium. This granulomatous inflammation proceeded to fibrosis (fig. 1); hence, the presence of scar tissue round a dilated or a ruptured segment of a collecting tubule (cf. fig. 6 from case 3) probably indicated a former site of deposition of calcium and necrosis.

Some calcium had been deposited as concretions. Such deposits were rare in the medulla in comparison with the amorphous type, but the scanty minute cortical deposits were all of this nature and were similar to small deposits to be described in cases 2 and 3.

Signs of general tubular obstruction were slight—a few dilated collecting tubules, occasionally with non-calcified casts. The convoluted tubules were swollen and hydropic, as if filled with glycogen. A few glomeruli in the outer cortex were undergoing regression and obliteration, but most looked healthy. No vascular lesions were seen.

Cases 2 and 3

The changes in the kidneys were virtually identical in the two cases. There were massive deposits of calcium in the outer medulla, especially in the boundary zone (figs. 2 and 3). There were also a few minute deposits throughout both medulla and cortex.

Amorphous deposits of calcium, like those in case 1, were present throughout the medulla, but many of the granulomas were at a more advanced stage, with more fibrosis and much greater dilatation of the collecting tubules—weakened, presumably, by damage to their basement membrane and by disintegration of the surrounding tissue.

Most of the deposits of calcium in the medulla, however, consisted of concretions of various sizes, and these looked deceptively like calcified hyaline casts obstructing dilated tubules (figs. 2 and 3). This impression of an intratubular situation was strengthened by the flattened cells lining some of the spaces in which the concretion lay, but examination of an early lesion (fig. 7) showed that such cells were mesenchymal and not tubular epithelium. Most of the surviving tubules were dilated collecting tubules with flattened but distinctive epithelium. Many were distorted, and some were almost obliterated by deposits of calcium immediately outside their stretched out epithelium; but others were widely dilated, despite the proximity of large concretions, and some contained hyaline non-calcified casts.

Inflammation at the sites of these calcified concretions was slight; in some of the small deposits there was a mild cellular reaction of histiocytic type, and around the large lesions tubules were compressed and atrophied and there was mild fibrosis. Some of the dilated collecting tubules contained a few polymorphs, but there was no other evidence of pyogenic inflammation.

The mode of evolution of the large deposits of calcium—in all three cases—can only be inferred by analogy with smaller lesions. Thus, in one of the smallest granulomatous lesions (fig. 4) amorphous calcareous material had apparently been precipitated not in but between the medullary tubules. The tubules were damaged and compressed; their basement membrane had disappeared; and their epithelial lining, attenuated and necrotic, was invaginated by the interstitial calcium now in direct contact with its outer surface. In another small lesion (fig. 5) the calcareous material was again interstitial, but here irregular concretions of varied size and density surrounded and compressed the adjacent limbs of Henle. Not all the calcium in such lesions was extratubular, however, for (as this figure shows) calcification had transgressed the basement membrane of one of the tubules and involved its epithelial lining cells but not the hyaline cast in its lumen.

A few of the concretions invaginating the epithelial lining of collecting tubules (fig. 3) appeared to lie between

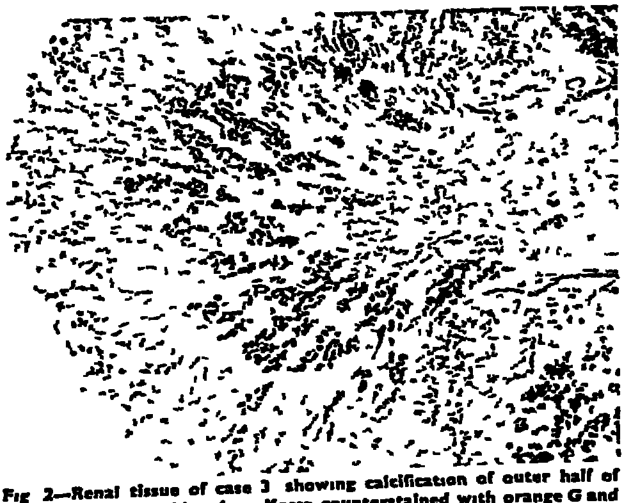

Fig. 2—Renal tissue of case 3, showing calcification of outer half of medullary pyramids. (von Kossa counterstained with orange G and neutral red. × 83.)

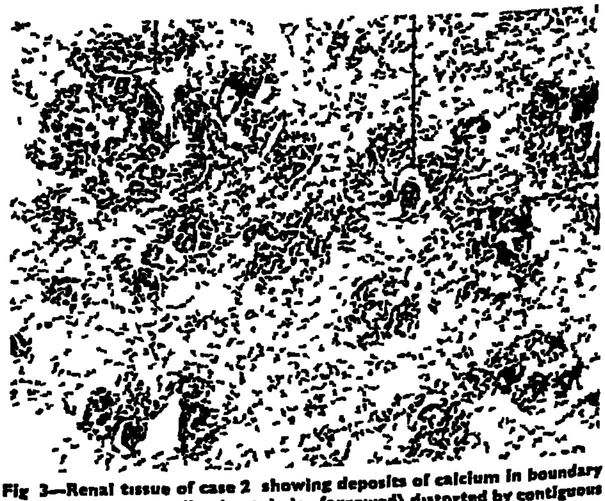

Fig. 3—Renal tissue of case 2, showing deposits of calcium in boundary zone, and cystic collecting tubules (arrowed) distorted by contiguous masses. (Hæmatoxylin and eosin. × 66.)

remove it if, on inspection, they found it to be diseased, to look unhealthy, to be kinked, to be adherent retrocæcally, or to contain fæcoliths A few commented that appendicectomy undoubtedly increased the risk of postoperative pyrexia and infection and that it was a complicating factor in the convalescence after hysterectomy

As a result, the following suggestions can be made

(1) *That British gynæcologists*, by a majority, do not advise routine appendicectomy when performing hysterectomy

(2) That this rule should not be followed unreasonably and the appendix, if obviously diseased or unhealthy, or if containing fæcoliths, is probably best removed

(3) That there is a real danger of local and general peritonitis, and that simultaneous appendicectomy and hysterectomy should be covered by a course of postoperative antibiotics

I acknowledge the kind coöperation of the members of the Gynæcological Travellers' Club and other colleagues who kindly, answered my questionnaire

FATS AND DISEASE

SIR,—Dr Sinclair's letter (April 7) intrigues me

In 1952 and subsequently we reported studies, begun in 1950, which showed a profound decrease in plasma cholesterol and phospholipids, in patients maintained on diets containing large amounts of unsaturated vegetable fats[1][2] Among the possible reasons for such an effect were considered (1) absence of cholesterol, per se, (2) a positive effect of some vegetable sterol, (3) a positive effect of vegetable phospholipid, (4) a positive effect of one or more fatty acids present in the vegetable fat

Over the intervening years, by a process of exclusion, all except the last have been essentially eliminated Studies in which fats of vegetable origin, but of very different iodine number, have been alternated in the diet have shown that the decrease in plasma cholesterol and phospholipid levels is directly related to the amount of unsaturated fat present in the diet[3] A very recent study, in which 100 g of a synthetic triglyceride, containing approximately 2 g of linoleic acid, has been administered daily,[4] further implements this conclusion

Dr Sinclair's observations regarding abnormal deposition of lipids in the skin under conditions of essential-fatty-acid deficiency are of considerable interest, as are his speculations regarding the very possible rôle of essential fatty acid and/or pyridoxine deficiency in the pathogenesis of degenerative vascular disease His observations regarding increased requirement for essential fatty acid in male animals may be particularly pertinent in this regard

The work of Shapiro and Freedman[5] on the relation of essential-fatty acid and methionine deficiencies to hypercholesterolæmia may help to clarify some of the observations of Best et al[6] and of Stare et al[7] on the atherogenic effects of deficiency of choline, of methionine, and of cystine

If one accepts as a working hypothesis the concept that transport of fatty acid is the major function of cholesterol[4] and recalls that the "normal" fatty acid, which is esterified with cholesterol, is an unsaturated acid,[8] it would seem not improbable that relative or absolute unavailability of essential fatty acids may result in "jamming" of cholesterol metabolism, with resultant increase in production and abnormal deposition of cholesterol If this concept be even partly correct, it is obvious that experimental efforts designed to evaluate the specific metabolic functions of essential fatty acids, per se, are important Such studies are under way in this laboratory

Dr Keys (April 28) is less than enthusiastic regarding the concept of the importance of essential-fatty-acid deficiency in the pathogenesis of atheromatosis Dr Keys says "We have observed this [i e, differential effects of different fats upon cholesterogenesis] as well as others, including Kinsell in California, Ahrens in New York, and, recently, Bronte Stewart in South Africa" Dr Keys until recently felt that fats were fats, and all were equally bad in regard to cholesterogenesis Since he appears to have accepted the weight of evidence for the profound differences in "cholesterogenic effects" between some animal and vegetable fats, we may expect that before too long he will decide that deficiency of essential fatty acids plays an important role in the pathogenesis of degenerative vascular disease

LAURANCE W KINSELL

SIR,—May I add my humble voice to the recent flurry of interest engendered by Dr Sinclair's letter on the possible multitudinous rôles of essential fatty acids in disease? Perhaps this series of letters should be entitled "Hard Fats and Hard Arteries"! Although we are living in an age of rapid advances and as rapidly crystallising opinions, the healthy controversy let loose may well mark the initial break-through in one aspect of the problem of atherosclerosis While I may be accused of speaking upon a subject to which I am a relative newcomer, my attention in the past three years has been devoted to orienting myself through the slough of fats, lipoprotein carriers (alpha and beta), S_f and S negative particles, Cohn fractions, phospholipids, lipid phosphorus, free and esterified fractions of cholesterol and their ratios, neutral fats and triglycerides, choline and methionine effects, and the relative incidences of arterial diseases in countries torn by war and altered by peace The purpose of this attempt at orientation was to find what approaches might lead to therapy, for our formerly hypertensive patients are no longer dying of their disease but of atherosclerosis and its manifestations

Out of these contemplations came a regression (because of confusion) to non-ultracentrifugal simples and to Aschoff's statement "From plasma of low cholesterol content no deposition of lipoids will occur even though the mechanical conditions are favourable"[9] Added to this might be "It may matter little how cholesterol and its esters are carried in blood, what is important is the blood level and the nature of the ester" Schonheimer's old but careful analyses of aortic plaques showed clearly that esters of cholesterol increased with severity of the lesions[10], several fatty acids were demonstrated, but the principal ones were saturated or monoethenoid (stearate, palmitate, oleate) The solubilities of cholesterol esters of unsaturated fatty acids are greater than are those of saturated acids with chains of equal lengths[11]

To my knowledge, Snapper was the first to suggest that deficiency of unsaturated acids might lead to atherosclerosis,[12] by pointing out the low incidence of the

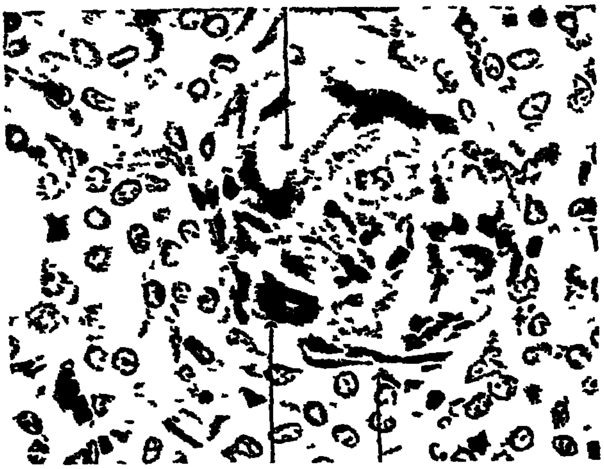

Fig 4.—Renal tissue of case 3, showing early and apparently intertubular lesion. Calcifying interstitial tissue is infiltrated with histiocytes. Tubules (arrowed) are compressed and show degeneration of epithelium and destruction of basement membrane. Top arrowhead lies on hyaline cast. (Hæmatoxylin and eosin × 535.)

the epithelium and the basement membrane. These concretions also are believed to have originated outside but up against the tubules, as in fig 7, for reticulin stains seem to show that the delicate intervening stroma may disappear and the once interstitial calcium now lies within the tubule, although still outside its epithelial lining. This illustration also shows how tubular distortion, comparable with that seen in the big deposits, can be produced from without by quite small interstitial concretions close to the basement membrane.

Cortical deposits of calcium were small and scanty. As in case 1, they appeared to be primarily interstitial, but in a few instances calcification had apparently involved some of the adjacent tubular epithelium. Signs of tubular obstruction within the cortex—dilatation of tubules and formation of hyaline casts—were less than would be expected from such gross medullary lesions, but the "bulk" of the convoluted tubules was considerably less than normal—the result, apparently, of atrophy or of failure of growth rather than of destruction. Most of the glomeruli were healthy, but some in the outer cortex were small and covered by prominent cuboidal epithelial cells and looked immature; a few of these superficial glomeruli also showed partial sclerosis, but there was no evidence of active glomerulitis. No vascular damage was seen.

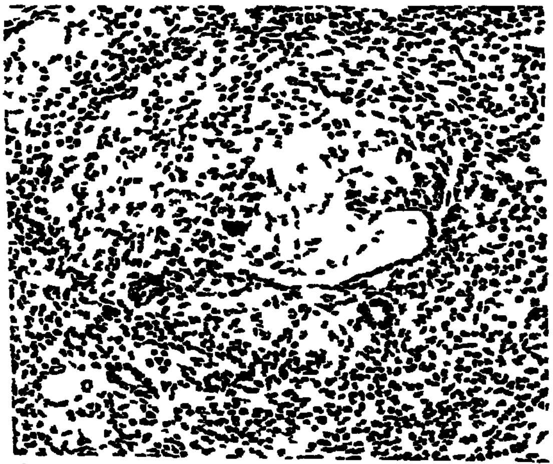

Fig 6.—Renal tissue of case 3, showing repair of focus of destruction in medulla. Cystic space in scar tissue is partially lined by epithelium and contains a large cast. Hardly any calcium can be seen. Giant cells, some possibly derived from tubular epithelium, are present in scar tissue. (Hæmatoxylin and eosin × 165.)

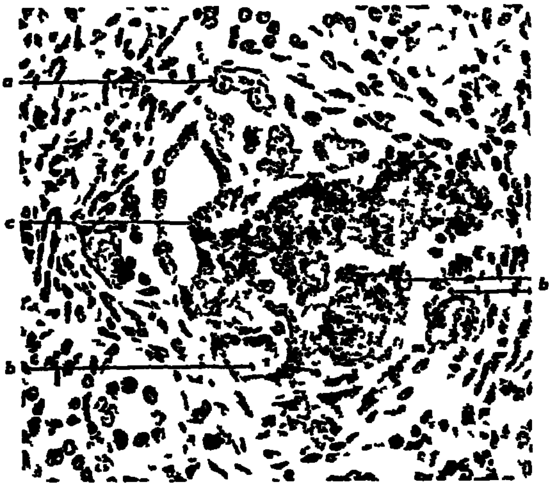

Fig 5.—Renal tissue of case 2, showing interstitial calcium concretions compressing tubules: *a*, laminated concretions; *b*, lumen of compressed tubules; *c*, calcification of epithelium of cast-containing tubule. (Hæmatoxylin and eosin × 275.)

DISCUSSION

The distinction between idiopathic hypercalcæmia of the simple type and infantile renal acidosis rests mainly on the biochemical findings. Thus, the normal values of the plasma bicarbonate level in cases 1 and 2 reasonably exclude renal acidosis. On the other hand, all the biochemical changes in case 3 could be found in either syndrome. Nevertheless, although the plasma-bicarbonate level is low, we accept the combination of a high plasma-calcium level, a normal plasma-chloride level, and an acid urine in the absence of dehydration as indicating idiopathic hypercalcæmia.

The two forms of idiopathic hypercalcæmia have been differentiated by clinical and radiological criteria since the biochemical changes do not provide a clear distinction. Despite their fatal outcome our cases conformed with the simple, so called benign, type. However, the validity of the criteria used is by no means certain, and gradations between the two forms are now being recognised (Russell et al. 1954). The peculiar facial appearance, believed by some to be distinctive (Schlesinger et al.

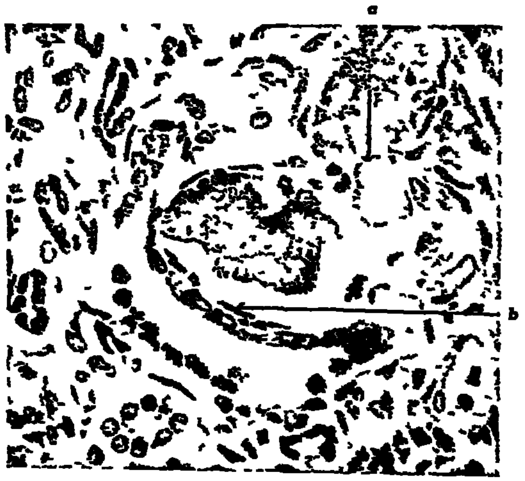

Fig 7.—Renal tissue of case 2, showing interstitial cast-like concretion distorting a collecting tubule. Another concretion, less intensely stained, is forming at *a*. Flattened cells (*b*) outside the tubular basement membrane line the interstitial "space" in which the concretion has formed. (Hæmatoxylin and eosin × 386.)

disease in Northern Chinese, their high dietary intakes of linoleate and particularly linolenate, and the high iodine number of their serum-lipids (mean 156.6, compared with about 110 for allergic individuals and 84 in our laboratories for atherosclerotic persons). He attempted to obtain a lipid chemist from this country for the purpose of measuring the degree of unsaturation in Chinese fat, when his work was interrupted by the Sino-Japanese war. Obviously, more studies on the iodine numbers of plasma lipids should be made. The fact that four groups of investigators (Ahrens et al.[13] in New York, Beveridge et al.[14] in Kingston, Ontario, Malmros and Wigand[15] in Lund, and Kinsell et al.[16] in San Francisco) and now a fifth (Bronte Stewart et al.[17] in South Africa) all have conclusively demonstrated marked decreases in total plasma cholesterol by feeding vegetable fats with high iodine numbers, leads one to the inescapable conclusion that synthesis, transport, or katabolism of this sterol is intimately affected by some constituent found in the oil and not in saturated animal fats. What is this substance?

Most of your respondents, as I did, have implicated linoleic acid. Dr. Sinclair himself suggests linoleic and arachidonic acids. There are discrepant experimental results inconsistent with this idea.

While the data is not complete, examination of the unsaturated fatty acid contents of the oils which lower plasma cholesterol, as listed in Deuel's comprehensive book,[11] usually contain linolenic acid, as well as the less unsaturated linoleate. Thus, soybean oil (3–11%) and corn oil (0.4%) are those most commonly used; the former is more effective in lowering cholesterol. Likewise, linseed (40–53%, the cake being used as a food in Eastern Europe and the U.S.S.R.), millet seed (6–8%), walnut (3.2%), beechnut (2.9%), mustard (2.7%), wheat, and rye are other sources of linolenate. Alcoholic extract of brain lowers plasma cholesterol[18]; it may contain at least one unsaturated fatty acid of the linolenate or arachidonate type. On the other hand, there is plenty of linoleic acid in one vegetable oil shown to raise plasma cholesterol—cottonseed oil (15%, equal to corn oil), as demonstrated by Prof. Ancel Keys. All of the cholesterol-raising fats listed by him are *deficient in linolenate*, although it is true that contents may vary according to the food intake (for animal fat) or the variety of plant, the climate, and the soil, which may account for discrepant results. Some of the oils used by Bronte Stewart contain linolenate, arachidonate, or longer chained more highly unsaturated fatty acids, with the possible exception of ground nut oil. For example, African sunflower seed oil probably contains linolenate, South American probably does not. Therefore, the common denominator of cholesterol lowering oils in man may actually be linolenate or a fatty acid of a higher degree of unsaturation, plus linoleate. Linolenate is a precursor of hexaenoate and linoleate of arachidonate.[19]

Bronte Stewart et al. obtained results with linolenic-deficient oils quite divergent from those obtained by others, especially in the case of olive oil, which usually raises plasma cholesterol. In fairness to their excellent and careful work, it is doubtful that a normocholesterolæmic Bantu would respond to an acute fat load in a manner identical with a hypercholesterolæmic Englishman or American. For the former obviously has a healthy cholesterol metabolism, while that of the latter is diseased to some degree or another, if we can believe the statistics. It is probable that the normal values of total plasma cholesterol are 100–160 mg. per 100 ml., higher values in Europeans and Americans representing disorder.

This attractive hypothesis, however, cannot account entirely for the atherosclerosis found so commonly in civilised persons all over the world, but often absent in the "uncivilised." The presence of extensive aortic calcification in some Egyptian mummies in the British Museum attests to its antiquity. In Japan, often cited as a sclerosis-free area, Kimura's careful study of 1007 necropsies showed gross coronary atherosclerosis of some degree in 80–100% of males of 35 years or older, although the incidence in 3600 less carefully studied cases was a little more than half that value in patients 65 and older. High-grade coronary disease, however, was present in less than 10%.[20] Similar incidences were found in Hawaiian orientals, although severe degrees were present in about half.[21] It is doubtful, therefore, whether we can attribute the presence or the absence of the disease to one factor—essential fatty acid deficiency—although this factor may be a strong influence in the severity and therefore the mortality rate through ischæmic and hæmorrhagic complications.

Not to confuse the point further, but merely to indicate other known influences of "civilisation" which may be accessory factors in abnormal cholesterol and fatty acid metabolism and in providing an intimal lesion in which cholesterol esters may deposit, we should not forget two. As Dr. Sinclair has well pointed out, vitamin B_6 or pyridoxal phosphate may be involved. This ubiquitous coenzyme not only acts as codecarboxylases and cotransaminases but promotes the conversion of linoleate to arachidonate and linolenate to hexaenoate in rats,[22] thereby increasing the unsaturation of partly unsaturated fatty acids. Furthermore, deficient states in monkeys result in subintimal lesions microscopically identical with those of early atherosclerosis[23][24] (providing a *locus* where lipids are deposited?), and deficient monkeys fed cholesterol exhibit much higher blood levels than do controls.[25] This heat-labile, light-unstable coenzyme is low in many processed foods, and many dietaries may be marginal during winter seasons.[26] Does a partly deficient man handle linoleate or even oleate less readily than one with adequate amounts of this vitamin?

The second influence is, strange to say, in trace metals. Pyridoxal probably requires a trace metal for coenzyme activity[27]; on two decarboxylases that metal is possibly zinc. Curran has shown that chromium increases hepatic synthesis of cholesterol and fatty acids in rats by 150%, vanadium depressing synthesis markedly[28] and even reducing aortic lipids by a half in cholesterol-fed rabbits.[29] Furthermore, a chelating agent which is not metabolised, ethylenediamine tetra-acetate, reduces plasma cholesterol markedly and rapidly when given intravenously and often reduces it to "Bantu levels" when given orally.[30] There are variable but often relatively large amounts of "abnormal" trace elements in American human tissues from all cities studied,[31] with fewer in American stillborn infants and traces to none in the tissues of "raw" African natives (I. H. Tipton, personal communication). Renal and hepatic cadmium, a decarboxylase inhibitor, chromium, tin, titanium, nickel, and lead are some of

[31] Tipton, I. H., Steiner, R. L., Foland, W. D., Mueller, J., Stanley, M. Oak Ridge National Laboratory Report, C. F. 54-12-66, Dec. 10, 1954.

1956), may indicate the severe type of illness, and certainly its occurrence has not been established in simple hypercalcæmia, it was absent from all our cases Radiography does not provide an absolute distinction, for osteosclerosis, present in all cases of the severe form, has been observed, albeit of minor degree, in the simple form (Creery and Neill 1954), it was not detected radiologically in any of our cases but was found at necropsy in case 1 Finally, a cardiac murmur, absent in all our cases, has been heard in infants with the simple type (Lowe et al 1954, Creery and Neill 1954) and has been absent in some cases of the severe form (Schlesinger et al 1956)

The renal lesion of simple hypercalcæmia is not specific, for interstitial and subepithelial calcification has been observed in infantile renal acidosis (Butler et al 1936, Doxiadis 1952) and as an incidental finding at necropsy in various diseases of infancy (A M Macdonald, personal communication) Glomerular immaturity and small tubular mass have also been noted in chronic renal acidosis of infants without renal calcification (Hutchison and Macdonald 1951) These features, in our opinion, are not the cause of renal calcification and may simply be the consequences of failure to thrive None the less the possibility of direct glomerular damage cannot be excluded in view of the findings in the severe form of the disease, these, according to Schlesinger et al (1956), may range from minute foci of calcification throughout the cortex and medulla to gross cortical destruction Admittedly the severe cases have been characterised by prolonged and recurrent urinary infection, but the glomerular lesions have apparently not been regarded as infective, and Schlesinger et al suggest that hypercalcæmia may itself cause glomerular damage The greatest glomerular and cortical tubular destruction was found in the three severe cases of longest duration, whereas in the fourth case (Dawson et al 1954) glomerular changes were as slight as in our cases of simple hypercalcæmia, which proved fatal at a comparable age

Mental retardation has been present in all infants with the severe type of idiopathic hypercalcæmia who have survived to the age of 2 years (Schlesinger et al 1956) but not in infants who have recovered from the simple type The three infants we have described did not appear to be mentally retarded, but all died within the first year of life Neuronal damage in one of the two brains examined at necropsy (case 3) was probably caused by terminal anoxia and not directly by the hypercalcæmic state Nevertheless the calcification of a cerebral artery in case 1 shows that there is a risk of cerebrovascular damage even in the simple form of idiopathic hypercalcæmia

Hypervitaminosis D presents striking resemblances clinical and biochemical, to idiopathic hypercalcæmia, Radiologically there are insufficient data in the published reports of vitamin D intoxication to allow an adequate comparison, nevertheless osteosclerosis comparable with that seen in hypercalcæmia of the severe type has been recorded (Hess and Lewis 1928, Ross 1952) The cause of osteosclerosis in the two diseases has not been established, but its appearance and regression in idiopathic hypercalcæmia seem to be related to episodes of impaired renal function (Harris 1954, Schlesinger et al 1956)

The diagnosis of hypervitaminosis D in fatal cases of renal calcification, such as those of Thatcher (1931, 1936) has been criticised by Wolf (1943), who considered that the dosage of vitamin in these cases was too small to cause metastatic calcification except in the presence of some underlying disorder—e g, severe renal disease By his own experiments, however, Wolf confirmed that vitamin D in large doses can cause nephrocalcinosis in "healthy" infants The role of vitamin D in Thatcher's cases cannot now be assessed, but review of the histological changes in the kidney has shown them to be essentially the same as in our cases of simple hypercalcæmia (A R Macgregor, personal communication), in which the daily intake of vitamin D was at least 2000 I U at the time of admission to hospital

The cause of death of our three infants was clearly not renal failure, despite the involvement of so many renal tubules by the deposits of calcium We believe that the death of the second infant was precipitated by acute bronchopneumonia and widespread pulmonary thrombosis, and, theoretically, the formation of thrombus—conceivably initiated by emboli from veins in the leg—might have been favoured by cortisone (Cosgriff 1951) as well as by the hypercalcæmic state No adequate explanation for the deaths of the first and third infants was found One factor common to all three was persistent vomiting which proved very difficult to control Even so, the plasma electrolyte levels did not indicate a biochemical disturbance serious enough to cause death Unexplained deaths have previously been recorded in idiopathic hypercalcæmia (Harris 1954, Dawson et al 1954), and equally mysterious deaths in hypervitaminosis D, with renal calcification as the only gross lesion, have been attributed to a direct toxic action of the vitamin (Bauer and Freyberg 1946)

However close the resemblance between the two conditions—and the facts are surely suggestive—the evidence implicating vitamin-D intoxication in idiopathic hypercalcæmia is at best circumstantial Nevertheless so many factors may enhance the toxicity of vitamin D (Wolf 1943) that, until the cause of idiopathic hypercalcæmia is found, the amount given to infants should be kept under constant review

Summary

The clinical and pathological features of three fatal cases of the simple form of idiopathic hypercalcæmia are described and compared with those of the severe form and of hypervitaminosis D

The deaths of these three infants have not been satisfactorily explained, but a fatal outcome may possibly have been precipitated by persistent vomiting

Renal calcification was the salient pathological feature in all three Most of the deposits of calcium were in the outer medulla, the cortex being only slightly affected Some of the medullary deposits appeared to be closely related to the loops of Henle and contained amorphous calcium, such deposits were *associated* with focal degeneration of both interstitial tissue and tubules and with granulomatous inflammation The rest of the medullary calcium, and the few small cortical deposits, consisted of concretions in the interstitial tissue, and these produced tubular compression and distortion

The renal lesions are not specific, similar changes having been found in cases ascribed to hypervitaminosis D and in infantile renal acidosis, as well as in association with various other diseases of infancy

Metastatic calcification of a cerebral artery and osteosclerosis were present in one of the cases

We are grateful to Prof J L Henderson and Prof A C Lendrum for their advice and criticism, and to Dr A R Macgregor and Dr A M Macdonald for their generous help and for allowing us to study their cases The histological sections and photomicrographs were prepared by Mr R S P Fawkes, A I M L T

the "abnormal"-*metals found, of which several are* apparently the results of "civilisation," showing marked differences in these three groups Some of these are antimetabolic Cadmium is especially high and accumulates with age Can an abnormal trace metal affect a pyridoxal enzyme system so as to cause a conditioned local deficiency ? If so, lipid metabolism might be altered

Therefore, intermittent or chronic deficiency of essential fatty acids in man, a distinct possibility in many areas of the world where atherosclerosis is endemic and almost universal, may be only one, albeit a large, factor in furthering the development of this most important disease It is possible that a high intake of saturated fats may produce deficiency when either intake is marginal or metabolic pathways are disturbed by exogenous influences On the other hand, we must not neglect biochemically related factors, of which trace metals and vitamin B_6 are two examples, for this disease is probably not the result of any one single disorder in all nations and races

We cannot wait, however, until all of the metabolic pathways of fatty acid, cholesterol, and collagen metabolism are clearly understood before attempting therapy by lowering plasma-cholesterol in man Tools are now offered which will do this without hazard or excessive inconvenience During the present interesting interim between the state of knowledge now and the advent of specific therapy, it has been our practice to lower blood-cholesterol in our patients by (*a*) reducing the intake of saturated fat by about 50%, (*b*) providing about 0 5 g linolenate per day by the use of soybean oil in salad dressing, sauces, and cooking, (*c*) giving the calcium complex of E D T A in doses of 1 0 g per day orally, and (*d*) giving an adequate intake of pyridoxine, on purely theoretical grounds (5 to 10 mg per day) It may be a long step, however, between low plasma cholesterol levels and demonstration of reversal of the arterial lesions

HENRY A SCHROEDER

CIRCULATORY FAILURE IN MARYLEBONE ?

SIR,—In some lowly invertebrates the blood vessels are traversed in both directions, though it must be conceded to the purists that this does not happen simultaneously Up the evolutionary scale arteries and *veins* are differentiated, the blood traffic, so to say, being one-way only

Your older readers will recall the happy, albeit primitive, days when the streets of Marylebone were coursed either North and South or East and West, and the traffic was contained With its rapid increase over the past years evolved a strange and hybrid vascular system of one way vessels, two-way vessels, and arteriovenous aneurysms No doubt some traffic-happy authority had hoped thereby to improve the circulation of this increasingly cyanosed area Instead there has been a further and polycythæmic increase in the number of (if I may be forgiven the term) carpuscles, anisocytotic and even crash crenated, trying to circulate along the narrowing vessels For, to complete the pathology, rows and double rows of parked cars line these vessels and are virtually becoming organised into plaques Spasmodic occlusion occurs frequently, and it can be only a matter of time before mass thrombosis ensues and the circulation fails completely

Traditionally Harley Street and its environs has long been a medical precinct, and, despite some invasion by office and flat, it remains predominantly medical But its streets are being used to saturation point as convenient all day parking places for the cars of business people and shoppers from the adjoining parts of the West End To the doctor trying to reach his *professional* rooms, and *the patient trying to meet him in consultation*, it becomes increasingly difficult and time consuming to penetrate its congested roads and to find a temporary resting-place for a vehicle

As the *New Statesman* was once described of Bloomsbury, so *The Lancet* might still be called the parish magazine of the Harley Street area This, Sir, is my reason for drawing your attention to the above troublesome and disorganising situation

Obituary

WILLIAM HENRY WYNN

M D Lond, M Sc Birm, F R C P

Professor Wynn's sixty years of work in the Birmingham medical school began when he entered it in 1895, at 17, having previously won a scholarship at Mason's College from King Edward's Grammar School, Aston His ability was at once evident he gained the gold medal in physiology in the London B SC , he won prizes both for an essay on altruism and for an investigation of the medullated sheath of nerve-fibres, and he founded the students' representative council In 1901, the year when he graduated M B Lond, his M SC (obtained by thesis) was conferred at Birmingham University's first graduation ceremony He became pathologist to the General Hospital in 1903, and in the following year joined its clinical staff as assistant physician, being only 26

This was a time when bacteriology was having a strong influence on medical practice, and with his experience in the laboratory Wynn was particularly interested in applications of the work of Almroth Wright and others As a consultant he was not among those who felt that their task was fulfilled when they had provided a diagnosis, and in his wish to offer effective treatment he especially studied vaccine therapy *Though much of what he attempted has since* been outmoded, it reflected his desire not only to attack disease at its source but also to do something for conditions then largely untreatable His house-physicians and many others will remember the injections of his P S I vaccine which he employed against acute pneu*monia*—then a formidable disease Chronic infections, particularly of the respiratory tract, were also treated with vaccines, and often with apparent success Wynn's acute mind was searching into the problems of infection and immunity His special interest in diseases of the chest was transmitted to many of those working for him and with him, and introduced them into a branch of medicine which has since burgeoned In 1910–12 he helped the late Sir John Robertson in setting up the *tuberculosis service of* Birmingham, and some of the credit belongs to him for the integration of dispensary and sanatorium, of the therapeutic and the preventive aspects of the attack He was appointed physician to the sanatorium in Yardley and adviser to the Derby County Council

In 1926 he succeeded J W Russell as professor of medicine at Birmingham, and his twenty years' tenure of the chair was parallel with the rise of clinical medicine in its present form, employing more and more ancillary methods He was active, for example, in the earliest use of X rays in Birmingham A tribute published last autumn in the university gazette says that Russell, during his few years as professor, had set a new standard in the discharge of academic duty and that Wynn followed his example despite the inevitable sacrifice and inconvenience it entailed

PARTIAL GASTRECTOMY FOR PEPTIC ULCERATION IN THE AGED

WHITTINGTON HOSPITAL, LONDON

"There is no one so old but thinks he can live a year"—Cicero

Safe elective surgery is making an increasing contribution to the care of the aged Advances in anæsthesia, antibiotics, nutrition, and techniques have made genito urinary, orthopædic, and cancer operations safe in the elderly The old are benefiting from surgery as well as the young To be freed from a handicap which conditions life, thinking, and relationships is a gift to the old and a joy for remaining years Gastric surgery has lagged behind other specialties in applying rational principles of treatment to the older patient

Peptic ulceration is no respecter of age or income group, and, though the usual onset is in the twenties, thirties, and forties the relapsing nature of the disease means that many old people suffer from it But in our experience many septuagenarians and octogenarians may show the disease for the first time often in a virulent form The old people frequently need surgical relief and should not be denied it solely on fullness of years Often they are good subjects They are almost all lean and have escaped the ravages of atheromatous accidents, which may have carried away their fatter and perhaps more sanguine brethren in their sixties

We wish to show that partial gastrectomy, the established and rational surgical treatment for chronic peptic ulcer, is feasible and safe in patients over the age of 70 In our experience these patients have been among our most grateful and gratifying

It is an accepted tenet in the treatment of malignant disease that a major operation, soon forgotten, is worth while even for a year of comfortable life Why not extend the principle to this undermining and debilitating complaint in which the sufferers may have several years of high quality life before them? As people grow older their interests often narrow, and life may even revolve around their gastric symptoms To do away with these symptoms raises their level of happiness, and their minds are free for more constructive purposes

We analyse here our experience in 30 consecutive cases of elective partial gastrectomy in patients over 70 and endeavour to answer some of the questions this thesis inevitably raises

Investigation

The history and clinical examination were the most important investigations Most patients had fifty minutes' history taking and ten minutes' physical examination In this way the disability caused by the ulcer was carefully assessed

All 30 patients had barium meals, and 29 had fractional test meals The barium meals showed evidence of ulceration in 29 cases, and in the 30th a shallow ulcer was seen at gastroscopy The test meals were not in any way conclusive but suggested what lesion was likely to be present The average top readings for gastric ulcer were 50/25 N/10 HCl, whereas the average top readings for duodenal ulcer were 75/45 The preoperative weight of all these patients average the low figure of 8 st, ranging from 5 st 9 lb to 12 st

INDICATIONS FOR SURGERY

Why operate on these patients? They have run their allotted span of three score and ten years The first and greatest indication is persistent symptoms Our operations were considered with the patients' symptoms in view A patient does not mind having a disease if he has no symptoms It follows that the greatest surgical symptom—pain—was our principal indication If there is constant and recurring pain and a history of a dramatic episode, such as bleeding or perforation, then the decision is easily made

The second factor is the insurance and prophylaxis that operation confers Mulsow (1941), reviewing peptic ulceration in the aged, found that 33% of the deaths due to peptic ulceration were in patients aged more than 60 Patients do not die from uncomplicated peptic ulcer, though it may contribute to other causes of death In gastric ulceration the spectre of carcinomatous change is always present, but the real threat to life comes from complications that require emergency surgery We have found that Cole's (1953) statement "The aged tolerate elective surgery well but emergency surgery poorly" is true The mortality of perforation and hæmorrhage in the aged is high, whether they are managed medically or surgically Hæmatemesis has a mortality of 15 9% in patients aged more than 70 (Fraenkel and Truelove 1955) Mortality mounts with recurrent incidents, and 4 of our patients had previous perforations or hæmorrhages Many patients survive emergency operations only to succumb to postoperative complications They will often stand an operation but fail to stand a complication

The third factor is physiological Old patients do badly with prolonged rest in bed, the traditional pillar of medical treatment There are many objections to this The dangers of mental deterioration, thrombosis, contractures, bedsores, anorexia, and constipation are now well recognised As well as this the repair destruction cycle has taken place so often that it is too much to expect that the mobile mucosa will ever be adequately restored Mechanically unsound duodenums and attenuated cicatrised lesser curvatures do not improve on rest in bed An exception to this is the giant gastric ulcer of late, possibly arteriosclerotic, origin, which often shrinks dramatically on medical treatment and may even be quite silent

Economics is another consideration A third of our patients had no other means of support than the old-age pension, and many more had little else These people could not afford to sustain indefinitely the long-tried gastric diet with its expensive egg-and milk basis We have learnt not to recommend chicken to old-age pensioners, they simply do not get it Cooperation for long-term medical treatment is not so readily obtained in later life when living habits have become fixed and more difficult to change

Most important is the patient's mental outlook The answer to such a simple and direct question as "How long do you want to live?" often brings an answer which helps in making a decision about surgical treatment In the earlier patients we found that the decision to operate was imposed on us, but increasing confidence based on success has enabled us to be more positive in our recommendations

PREOPERATIVE CARE

Vital capacity and hæmoglobin were estimated and improved on if possible Supervised breathing exercises-

NEUROMUSCULAR DISORDERS

Infantile Spinal Muscular Atrophy

Of the 67 patients in this group 29 were male and 38 female. In seven families there was more than 1 case in a sibship, but no case in a previous generation had occurred within living memory; the genetic pattern was compatible with the accepted autosomal recessive mechanism of inheritance. In two sibships containing more than 1 case the disease began at birth or shortly afterwards in each patient.

In 33 (50%) of these cases the disease was present at birth or began in the neonatal period. In the remaining 34 cases it began at some time between the second month and the end of the first year of life, except for 1 case in which weakness appeared to begin early in the second year. The age of onset made little difference to the natural history of the illness, which was usually inexorably progressive; the downhill course was perhaps more rapid in the cases of early onset. Within the period of follow-up 55 of these patients had died, invariably of respiratory infection; the earliest age at death was 5 weeks, the latest 12 years, but most patients died between the third month and the end of the fourth year. The 12 surviving patients were aged 4, 5, 5, 7, 7, 9, 9, 9, 11, 11, 12, and 20 years on follow-up. All were severely disabled with severe muscular atrophy, contractures, and skeletal deformity, but in many of them the disease had been apparently stationary for several years.

Although the age of onset and the tempo of the disease varied considerably, the clinical picture was remarkably uniform. In infancy these patients had often been at first sight healthy, well nourished, and intelligent. It was only on closer examination that the severe symmetrical progressive paralysis of the trunk and limb muscles had become evident. They had tended to be virtually immobile, with the arms abducted at the shoulder and flexed at the elbow and lying on either side of the head, and the legs flexed and externally rotated at the hips, with the knees flexed. This position taken up by the limp and hypotonic baby is characteristic. Spontaneous movements had been few and small in range, and the baby could not lift his head or turn over. If lifted the baby would hang loosely or "slip through the hands." The striking hypotonia of the paralysed muscles could be demonstrated by the remarkable range of joint movement: the feet could be placed behind the head, or the fingers turned back to touch the forearm. The deep tendon reflexes were usually absent or greatly depressed. Many patients had fasciculation of the tongue, and some, at an advanced stage, had paralysis of the pharyngeal muscles, with dysphagia and pooling of secretions in the pharynx. Intercostal weakness was often profound and respiration became purely diaphragmatic, with the result that a striking recession of the lower ribs during inspiration (at the diaphragmatic attachment) was almost invariable. Those children who survived beyond the first year soon lost their "puppy-fat" and widespread muscular atrophy became clearly evident. Some muscles were thin and thread-like and, after several years, virtually gave place to rigid fibrous tissue; others retained a few contractile elements under voluntary control, and some of these fasciculated freely. Hypotonia persisted until the unequal atrophy and inevitable increase of fibrous tissue caused contractures, bringing in their wake severe deformities of the spinal column, pelvis, and limbs.

The affected muscles were tested electrically in 23 of these cases and usually revealed loss of the faradic response; intensity-duration curves in 5 cases revealed complete or incomplete denervation of the muscles tested. Of 10 cases subjected to electromyography 4 showed spontaneous fibrillation; the interference pattern of maximal voluntary effort was greatly reduced in all the cases, but the surviving motor units were either normal or above average in amplitude and duration.

Specimens of muscle were obtained by biopsy in 10 cases and at necropsy in 5 others. In all of these specimens the characteristic findings of denervation atrophy (grouped uniformly atrophic fibres) were noted. In all the necropsy cases the number of anterior horn cells was severely reduced.

Benign Congenital Hypotonia

This term is used as a descriptive title for the syndrome which was observed in a total of 17 cases; all patients in this group showed an initially similar clinical picture, but 8 of them recovered completely while 9 showed some improvement but remain moderately disabled. Hence the natural history of these cases somewhat resembles Oppenheim's original description of *amyotonia congenita*, but the new title of benign hypotonia is preferred in view of the unfortunate connotations acquired by "amyotonia" since it was originally introduced.

Cases with complete recovery.—All 8 patients in the group were limp, floppy babies and all have recovered completely. At the time of follow-up the 3 males were aged 7, 8, and 11 years, and the 5 females 11, 12, 16, 16, and 18 years.

In each case amyotonia congenita had been diagnosed in infancy or early childhood because of failure to sit up, walk, or pass other physical milestones at the normal age; on examination at the time of the original diagnosis these babies had all been limp and floppy. There had been usually striking hypotonia of the muscles of the limbs and trunk, with pronounced hypermobility of joints. Although the severity of the abnormality varied from case to case, the over-all clinical picture and the natural history of the disorder in these cases were again relatively uniform. In contrast to the cases of spinal muscular atrophy, these babies had not been paralysed but had made spontaneous movements of the limbs and trunk, even though these movements seemed comparatively ineffectual compared with those of a normal child. None of them experienced any significant impairment of respiratory movement. Each of these children began to walk between the ages of 20 months and 5 years and thereafter made slow but steady progress, though for several years they were clumsy, tended to fall frequently, and could not climb stairs easily or keep up with other children of the same age. Eventually, however, all of them were normally active and on examination showed no neuromuscular abnormality or hypermobility of joints.

Electrical stimulation of the muscles in 5 of these children gave normal results, but in 2 cases electromyography in infancy had shown excess of polyphasic potentials on volition. Specimens of muscle obtained by biopsy in 2 of these cases and stained with hæmalum and eosin showed no abnormality.

The condition which afflicted these children corresponds closely to the recorded descriptions of essential hypotonia (Sobel 1926, Lidge 1954); the fact that they recovered excludes that form of joint hypermobility (Finkelstein 1916, Key 1927, Sutro 1947) which is unaccompanied by delay in development or muscular weakness, is often familial (as is evident in certain families of contortionists), and persists throughout life. The present cases are reported in detail elsewhere (Walton 1956a). My observations have led me to believe that laxity of joint ligaments was not an important factor in these cases; rather, their condition appears to have been due to a widespread congenital muscular hypotonia of undetermined ætiology which eventually recovered completely.

Cases with incomplete recovery.—Of the 9 surviving patients in this group 4 were male and 5 female, and at the time of follow-up they were aged 6, 6, 7, 11, 11, 15, 17, 30, and 53 years. Amyotonia congenita had been were taught to each patient, and careful inquiry was made into the possibility of the presence of a "cold" and, if such were found, operation was postponed for at least ten days after the acute infection Trial doses of any drugs likely to be used, such as pethidine and promethazine, were given

Most of our patients with recent symptoms of ulcer activity were given two or three weeks' rest in bed during these investigations, for we have learnt that there is a world of difference in the safety with which one can close the necrotic as opposed to the fibrotic duodenum, and the extra rest in bed *often converts the necrotic to the fibrotic* We have also the greatest respect for the giant posterior lesser curve gastric ulcer penetrating the pancreas—we prefer to remove it when healed

"KEEP DEATH OFF THE TABLE"

Half the cases were operated on under local anæsthesia Almost half the remainder underwent balanced anæsthesia of "local" infiltration with light general anæsthesia We used an anterior field and splanchnic block with 1 in 2000 amethocaine hydrochloride We have given up using adrenaline in the solution because of its occasional tendency to initiate auricular fibrillation, we have seen no toxic effects as a result of this Premedication that is accurate in timing and dosage is essential for success, and pethidine and promethazine as adjuvants are most useful drugs

The use of local anæsthesia presupposes an accurate established diagnosis and a planned operation Trauma, fumbling, and purposeless movements must be avoided More patients are suitable for local anæsthesia than are surgeons To have a conscious patient with one in the theatre is to be *constantly reminded of the fragile nature* of the person entrusted to one's care This is so easily forgotten under general anæsthesia, especially when one is confronted with some unusual technical problem

Paul, of Liverpool, said "Gentleness comes from the heart rather than from the hand" Under local anæsthesia gentleness is essential, and one quickly learns which are the *traumatising parts of the operation* Unnecessarily moving heavy retractors upsets the patient as much as does ligature of the left gastric pedicle

For the firm surface of the average operating table was substituted an inflatable 'Lilo,' which is much more comfortable for the patient and reduces the possibility of phlebothrombosis Comfort is important because nearly all these operations took longer than two hours When possible the patient was transferred from the operating table direct to bed

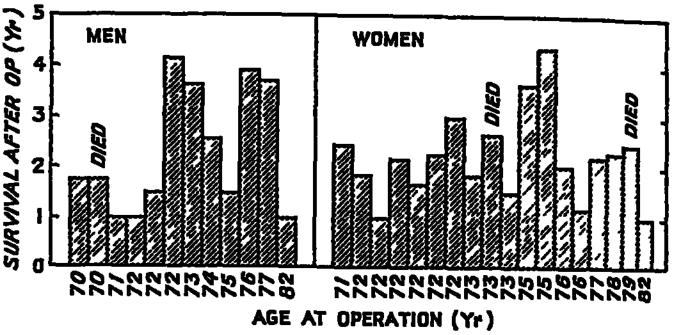
From our experience of emergency surgery for gastrointestinal hæmorrhage in the aged we have learnt that, in some cases where the tissues look poor, it is well to reinforce our two layer catgut anastomosis with a third layer of interrupted linen, thus forestalling the serious risk of delayed healing Before we close the abdomen, the splenic area is checked for the presence of blood, because a few ounces left to pool here may help to start an atelectasis at the left base

AFTERCARE

'In the aged more than half the postoperative deaths are due to bronchopneumonia" (Carp 1948), and we are constantly mindful of this Intramuscular penicillin 250,000 units six-hourly is given routinely for five days

So far as possible we try to have the same nurses caring for the patient, and the position of the bed in the ward is not altered This helps to prevent a confusional state

Most of the patients did not have an intravenous infusion, which tends to immobilise them, where it was essential, an effort was made to have a temporary rather than a continuous drip Rectal fluids are absorbed well by the prepared colon, and this was the method most often used during the first seventy two hours



Survival after operation

A close watch is kept for phlebothrombosis, and early mobilisation is tempered with discretion and mercy, *older tissues take longer to repair* Diarrhœa is a most serious complication in old people, and a "wait and see" attitude to it may be dangerous

Our patients left hospital after twenty-one days, and many had a further two weeks' convalescence

THE PATIENTS AND THEIR LESIONS

30 patients aged more than 70 had partial gastrectomies in four and a half years from February, 1950, to August, 1954 18 were women and 12 men In 10 the only means of support was the old-age pension

17 had gastric ulcers, 8 had duodenal ulcers, and 5 had signs of both Of the 17 gastric lesions 12 were in women, and of the 8 duodenal lesions 6 were in men Of the 5 patients with combined lesions 4 were women, 2 had their operations for duodenal ulceration, 1 for gastric ulceration, and the remaining 2 because of the combination 10 of the patients had duodenal ulcers alone or combined with an element of stenosis

An interesting subgroup were 4 patients who had hour-glass stomachs Their histories were from fifteen to thirty-five years, the average being almost twenty five

12 of the gastrectomies were of the Billroth I pattern, and the remainder were Polyas with a Finsterer Lake valve

The survival of the patients is charted in the accompanying figure

IMMEDIATE COMPLICATIONS

Death is the most important complication of operation There were no deaths immediately or remotely connected with the operations There were 2 severe chest infections 1 paralytic ileus was overcome by aspiration and intravenous fluid We had 1 burst abdomen

FOLLOW UP

All our patients were followed up as outpatients or visited in their homes by one of us 3 now have incisional hernias

From one to five years after operation the average of 27 hæmoglobins was 91%, and only 2 were below 80% In 13 patients the weight was unchanged—i e, within 7 lb of their preoperative weight 8 *gained* weight, the average gain being 14 lb, with a maximum of 23 lb 6 lost weight, the average being 12 lb and the maximum 19 lb There were no jejunal ulcers, actual or presumed, at the end of the period

Most of the patients were delighted with their operation, and on the whole we considered that their capacity was normal and that they were less liable to have post gastrectomy symptoms than are younger folk *Perhaps* this is because the gastric remnant is more lax and distensible in *older* people "Wonderful," "Never diagnosed at the age of 10 years in the patient aged 30 at follow-up, and at the age of 28 in the female patient aged 53 at follow-up.

Each of these patients had been a limp hypotonic baby, with an initial history strikingly similar to that of the cases, reviewed above, which recovered. Although they showed this picture of the "rag-doll" baby, spontaneous movements of the limbs were fairly good, and the striking flaccid weakness of infants with spinal muscular atrophy was not observed. Furthermore, the deep tendon reflexes were generally present, though depressed. All of these children were late in reaching their physical milestones and did not walk until aged from 18 months to 5 years. Even then they were clumsy and fell frequently, and all their muscles seemed small and weak. They all showed some improvement after first beginning to walk, but this improvement was arrested, and although they were able to carry out most everyday activities they remain moderately disabled. The 2 oldest patients said that their muscles had always been "generally weak" but there had been no change in their condition for many years.

On examination at follow up a uniform pattern of abnormality common to all the cases could be discerned. In all of them the skeletal muscles generally were abnormally small and slender and considerably weaker than normal; the upper facial muscles were involved in 3 cases, and the sternomastoids were usually particularly thin, more so than the posterior cervical muscles. In 2 cases the intercostal muscles seemed to be weak. The muscular abnormality was otherwise similar in the limbs in all the patients, except that in 2 of them the distal muscles were more powerful than the proximal. There was some evidence of persisting muscular hypotonia and of hypermobility of joints in all the cases, although this was slight in the 2 oldest patients. In 3 of the children, however, it was still striking at the ages of 6, 7, and 11 years. The tendon-reflexes were usually present, though sometimes depressed; in the patient aged 53 they were remarkably brisk. In 1 case there were slight contractures of the tendo Achillis, but serious deformities were uncommon; there was a moderate dorsal kyphoscoliosis in 3 patients.

Electrical testing of the muscles revealed no significant abnormality in 4 cases, but a pattern suggesting myopathy (numerous polyphasic and short duration potentials on volition) in 3 cases. Despite this finding muscle biopsy in 4 cases (including 2 of those with the "myopathic" electromyograms) showed no abnormality.

The resemblance of these cases to the benign congenital myopathy of Turner (1940, 1949) is striking. They correspond even more closely to Krabbe's (1946) description of congenital universal muscular hypoplasia. As Ford (1952) has pointed out, the only difference between the descriptions of Krabbe and Turner was that in 1 of Turner's cases muscle biopsy gave findings compatible with a myopathic disorder, whereas in Krabbe's case the muscle was histologically normal. In Turner's case, however, there was a complicating disease (bacterial endocarditis) which could conceivably have been responsible, at least in part, for some of the pathological changes in the muscles. The resemblance of these cases to the 8 described above which recovered completely is even more close and the only difference seems to be one of severity.

These observations suggest that the syndrome of "benign congenital hypotonia" is due to a congenital abnormality or pathological process which gives rise to profound muscular hypotonia, without paralysis, at, or soon after, birth. In some cases the patient recovers completely with the passage of time, while in others recovery is incomplete and the patient survives with small, weak, hypotonic muscles throughout life. It seems probable that the syndrome which Turner called "benign congenital myopathy" and that entitled by Krabbe "congenital universal muscular hypoplasia" should be included in this group. I do not believe that these children are suffering from a true myopathy or muscular dystrophy. This argument is developed, and cases are reported in detail, elsewhere (Walton 1956a).

Congenital "Myopathy" with Myasthenic Features

This case was in a patient who corresponded in many respects to Turner's description of "benign congenital myopathy" but also showed pathological fatigability, a persistent improvement in strength on treatment with ephedrine, and a temporary response to neostigmine (Walton et al. 1956). In this patient, too, the histological changes found on muscle biopsy were minimal, and it is doubtful whether she could be considered to have a myopathy in the accepted sense of the term.

Adams et al. (1953) suggest that some cases of recovery from amyotonia congenita may have been examples of infantile polyneuritis. No such case was recognised in this series.

Progressive Muscular Dystrophy

These 3 patients (all male) had apparently been normal at birth, but during the first year their limb movements had seemed to become weaker and the muscles flabby. In 2 of the cases there had been severe muscular hypotonia and some hypermobility at the joints; this finding, combined with the flabbiness, had led to the diagnosis of amyotonia congenita. All 3 infants had begun to walk late (at about the age of 2 years) and had then been clumsy, had waddled, and had fallen frequently. Subsequently their walking had deteriorated, and on follow up examination late in the first or early in the second decade they showed the characteristic features of the Duchenne type of muscular dystrophy, which begins in the first year of life in a significant proportion of cases; but hypotonia is an uncommon manifestation (Walton and Nattrass 1954).

Polymyositis

1 female patient had been noted to have weak limp muscles soon after birth, but without skin changes or pyrexia; she had not begun to walk until the age of 2 years and even then had been clumsy and had fallen frequently. She had become progressively weaker and developed contractures at the knees, elbows, and ankles; at the age of 8 years she became unable to walk because of increasing weakness and deformity of the limbs. Muscle biopsy revealed areas of degeneration and necrosis of muscle-fibres and inflammatory-cell infiltrates, with a striking increase in fibrous tissue—the picture of so called chronic myositis fibrosa, which I believe to be simply a chronic form of polymyositis (Walton 1956b).

Bovet (1936) described a case of acute polymyositis in an infant with the clinical picture of amyotonia congenita, but this experience seems to be uncommon.

CEREBRAL DISORDERS

"Cerebral Palsy"

Of the 6 patients 3 were male and 3 female; 4 had been born after a difficult assisted labour and had been cyanosed at birth. Subsequently, all 6 had been slow to develop and to pass their physical milestones. Amyotonia congenita had been diagnosed because of paucity of spontaneous movements, or lack of purposive activity, combined with general hypotonia of the limbs; there had been some hypermobility at proximal joints in 3 cases. In all the cases, however, the deep tendon-reflexes had been present and often active at the time of diagnosis. No case of this type showed the symmetrical immobility and respiratory difficulty seen in cases of spinal muscular atrophy.

On examination at the ages of 5, 8, 9, 11, 12, and 17 years 3 of these children were mentally backward, whereas the others were of normal intelligence. 2 showed better in my life," "New lease of life," "Not so well for years," "Christmas dinner with all the trimmings"—these are fair sample comments Our one poor result was in a woman whose ulcer did not show on barium meal but was discovered on gastroscopy Postoperative gastric biopsies show that she has a concomitant gastritis, and this rather than the ulcer is probably the cause of her symptoms

3 patients have since died Their deaths have been unconnected with surgery Cerebral thrombosis claimed one, a carcinoma of the splenic flexure with hepatic secondaries claimed another at the end of two and a half years, and the 3rd died of coronary thrombosis associated with chronic myeloid leukæmia after twenty one months

Partial Gastrectomy as Operation of Choice

Almost two-thirds of our patients had gastric ulcers Here the choice was simple it was either gastrectomy or nothing

The most contentious part of this paper is the selection of partial gastrectomy as the surgical procedure of choice for duodenal ulceration

Partial gastrectomy is the long established rational treatment, whereas gastro enterostomy is largely discredited at present But gastro enterostomy is often recommended for the aged, it is said to be quicker, safer, and equally effective Yet speed is not an important factor in a gastric operation, and shock is no longer a complication of gastrectomy Gastro enterostomy is not safe, because it is not equally effective After operation the patient may get relief of symptoms but is subject to the same lethal complications of peptic ulceration as before He is subject to the same complication that has led to the abandonment of gastro enterostomy in younger people—the hazard of marginal ulceration We could trace no evidence that older people are less liable to marginal ulceration The issue with which it has been confused is that there is a decrease in gastric acidity coincident with the advance of age, especially in men (Vanzant et al. 1932) But peptic ulceration in general is as common in the aged as it is in other age groups

> "10% cases of peptic ulceration occur in persons over sixty The age distribution of the general white population of the United States is just 10 8% over the age of sixty" (Mulsow 1941)

Our opinion is that, although the gastric acidity is decreased, the mucosal resistance is also decreased, and the end result is peptic ulceration

The proof that jejunal ulceration develops after gastro-enterostomy is from fact and inference

> Kiefer and McKell (1947) found 4 jejunal ulcers following gastrojejunostomy in patients aged more than 65 2 of these ulcers occurred in patients whose initial symptoms of peptic ulceration began at the age of more than 70
>
> One of us did a low Polya gastrectomy as an emergency for bleeding from a duodenal ulcer in a man aged 71, a year later he had a further operation for closure of a perforated anastomotic ulcer
>
> Charles Wells (personal communication) writes "Even the development of pyloric stenosis is an indication of continued activity The element of fibrosis is by no means an indication of diminished virulence The incidence of marginal ulceration after gastro-enterostomy is no less in old people than it is in the young"
>
> Ivor Lewis (personal communication) says that, if the duodenum is opened as the first step of the operation in cases of pyloric stenosis, one will nearly always find an actual ulcer still present This proves the dangers of stomal ulceration, which he found 'fairly frequently'

Decreased acidity is often caused by the gastritis which is secondary to pyloric hold-up When this is overcome by gastro enterostomy without attention to its precipitating factor, peptic ulceration, the gastritis resolves and the acidity increases again

Conclusions

Given adequate indications and careful preparation, surgical treatment for peptic ulceration in old people is safe

Partial gastrectomy has given promising results in our hands

Summary

Peptic ulceration, recurrent or new, is common in the aged, they stand its complications poorly

When elective surgery is indicated, we believe that partial gastrectomy is the operation of choice

30 consecutive elective partial gastrectomies in patients aged more than 70 are reviewed There were no deaths due to operation All of these patients have been followed up

We wish to thank Professor Wells and Mr Ivor Lewis for their personal communications

SPORADIC NON-ENDEMIC GOITROUS CRETINISM

HEREDITARY TRANSMISSION

James H Hutchison

Endemic cretinism results from a severe lack of iodine over several generations and is almost invariably associated with goitre The common type of sporadic non-endemic cretinism, on the other hand, is not associated with goitre, indeed it is usually considered to be due to an embryonic defect in the development of the thyroid gland (Dorff 1934), which is often assumed to be absent Nevertheless radioactive iodine (^{131}I) studies of cretins who, on clinical examination, seem to have no thyroid tissue at all have sometimes revealed enough ^{131}I in the neck to suggest that some thyroid tissue is present (Quimby and McCune 1947, Silverman and Wilkins 1953), which may be either ectopic or undescended (McGirr and Hutchison 1955), confirming an early anatomical observation in cretinism (MacCallum and Fabyan 1907)

The underlying cause of sporadic cretinism remains unknown Childs and Gardner (1954), who, seeking evidence of a hereditary tendency, investigated the families of 90 cretins, found that, though there seemed to be such a tendency, a familial prevalence was distinctly uncommon Consanguineous matings among the parents of the cretins was not strikingly commoner than in a control series of normal children

In contrast to this type of sporadic cretinism is what has been described as "sporadic cretinism associated with goitre" In this type of case familial prevalence and consanguinity of the parents are common (Osler 1897, Lerman et al 1946, Hurxthal 1948, Stanbury and Hedge 1950, Hubble 1953, McGirr and Hutchison 1953, Wilkins et al. 1954, Hutchison and McGirr 1954, Sexton and Mack 1954, Stanbury et al 1955a, 1955b), but isolated the signs of flaccid diplegia, and 1 of mild spastic diplegia; 1 had spastic diplegia with athetosis and cerebellar ataxia; and 2 had double athetosis.

Mental Defect

In 8 cases (5 in males and 3 in females) amyotonia congenita had been diagnosed because of failure to pass the physical milestones at the normal age, combined with moderate generalised muscular hypotonia. Hypermobility of joints had not been striking in these cases, and the deep tendon-reflexes had been present in all, but they had been limp flabby babies and had made fewer spontaneous movements than does the normal child.

On examination at the ages of 2, 7, 8, 9, 10, 12, 14, and 14 years 2 of these children were imbeciles, and moderate hypotonia of the musculature persisted, although there were no other neurological signs. 4 patients were feeble-minded and their skeletal musculature remained somewhat flabby; another was a hyperkinetic backward child with subaortic stenosis; and another showed moderate mental defect, congenital nystagmus, and severe myopia, but no neuromuscular abnormality.

NUTRITIONAL AND METABOLIC DISORDER

Scurvy

The 2 children with scurvy were twin sisters who showed severe muscular flabbiness and lack of spontaneous movement during the first 8 months of life. They improved rapidly on treatment with ascorbic acid after radiographs had revealed probable scorbutic changes in the limb bones, and the diagnosis had been confirmed by the blood-ascorbic acid levels. On examination at the age of 8 years they were healthy normal children.

No other examples of severe muscular hypotonia due to nutritional or metabolic disturbances in infancy were noted in this series; but I have subsequently observed manifestations of this type in a case of glycogen storage disease—an event previously described by Clement and Godman (1950) and by Krivit et al. (1953).

SKELETAL AND OTHER CONGENITAL DISORDERS

Arachnodactyly

The child with arachnodactyly had had loose hypotonic hypermobile limbs in infancy, but spontaneous movements had been good and vigorous, and she had begun to walk at the normal age, though she had tended to be clumsy. On examination at the age of 15 she was healthy and active, without any neuromuscular abnormality; but she had long spidery fingers and toes, hypermobility of her joints, and a high arched palate. Her father was similarly affected.

Multiple Congenital Defects

The girl with multiple congenital defects had also been limp and flabby as a baby and had begun to walk late. On examination at the age of 8 years there was no evidence of neuromuscular disease; there was a mid-dorsal scoliosis, and radiography revealed that T4 was a hemivertebra and the left 4th rib was absent; she also had dextrocardia. Hypotonia in congenital heart disease, such as Fallot's tetrad, has been described by Davison and Weiss (1929).

Congenital Dislocation of Hip

The diagnosis of amyotonia congenita in the patient with a congenital dislocation of hip was clearly a diagnostic error; lack of mobility and some hypotonia of the lower limbs, particularly the left, were later found to be due to dislocation of the left hip, and the patient made good progress once this was treated.

OTHER DISORDER

Spinal Ganglioneuroma

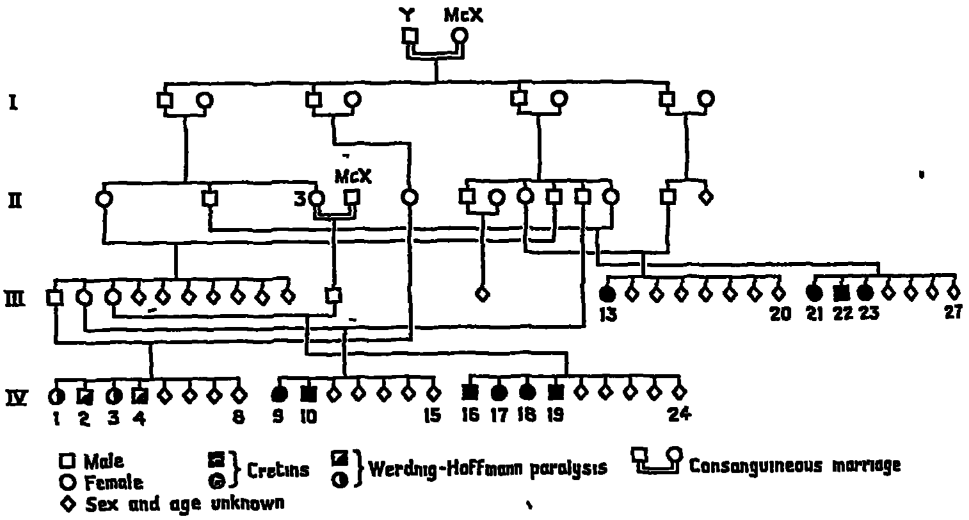
Progressive flaccid paralysis of the lower limbs in a male baby aged 6 months was later found to be due to a spinal ganglioneuroma.

Discussion

Brandt's (1950) conclusion—that the syndrome of amyotonia congenita, when taken to include all cases of generalised muscular hypotonia observed at, or soon after, birth, is due to many underlying disorders and not to a single disease—is confirmed by the findings in the present cases. It is evident that many babies presenting with this syndrome have spinal muscular atrophy and show the same inevitable deterioration as do those in whom the muscular weakness develops late in the first year. Although a few such babies survive for many years, and the disease appears to become arrested in some, yet without exception the children are left severely disabled and incapable of useful activity. In the infant afflicted with this disease muscular hypotonia and hypermobility of joints are profound; there are progressive impairment of spontaneous movement of the limbs and difficulty in respiration owing to intercostal weakness; the tongue may be seen to fasciculate; the tendon reflexes are absent; and bulbar paralysis may ensue. In an advanced stage the flaccid immobile baby, with shallow yet laboured respiration and "rattling" of secretions in the pharynx, presents a picture so characteristic that it cannot be confused with any other disorder.

In an earlier stage of the illness, however, diagnosis may be much more difficult because many other conditions may give a similar picture of muscular hypotonia. In benign congenital hypotonia this manifestation may be striking and the baby may be almost as limp and floppy as one with spinal muscular atrophy. On the other hand, these infants are not paralysed; though weak and late in developing they generally show a good range of spontaneous movements of the limbs. Respiratory difficulty is uncommon; even when present it is never so severe as in cases of spinal atrophy. Furthermore these patients show neither fasciculation of the tongue nor bulbar paralysis, and the tendon reflexes are usually retained, though they may be depressed. Clearly it is important to distinguish cases of this type from those with spinal muscular atrophy at the earliest possible moment, for their outlook is much more favourable. Negative findings on muscle biopsy may be of the greatest value in this context; in my experience biopsy in a case of spinal muscular atrophy never fails to show the characteristic appearances of denervation atrophy. I can offer no suggestion as to how to distinguish between the cases of benign congenital hypotonia which recover completely and those which improve but remain moderately disabled, except by follow-up studies. I have the impression that it is the less severely affected cases which recover completely, but at the moment this is no more than an impression. The nature of the neuromuscular abnormality in these cases is unsolved. Coers and Pelc (1954) have found that in 1 case of "amyotonia congenita" (which may have been of this type) the motor nerve endings, stained intravitally with methylene-blue, were "immature." Much work remains to be done before the significance of this finding can be appreciated, but it seems possible that this syndrome of benign hypotonia may result from varying degrees of abnormality in development of the neuromuscular apparatus. It appears that the term "benign congenital myopathy" (Turner) is a misnomer for cases of this type if "myopathy" is taken to mean, in its usual sense, "muscular dystrophy."

There remain to be considered the various cerebral, nutritional and skeletal disorders which in some of the present cases gave rise to generalised muscular hypotonia in infancy. It is evident that, although these children were limp and flabby and tended to "slip through the hands," the hypotonia and joint hypermobility were never so striking as in the cases of spinal atrophy. Nor, on the whole, were they so noticeable as in the benign



Pedigree of itinerant tinkers, showing appearance of goitrous cretinism and Werdnig Hoffmann paralysis

cases without any apparent familial prevalence have also been reported (Osler 1897, Hamilton et al 1943, Stanbury 1951, McGirr and Hutchison 1953, Wilkins et al 1954, Hutchison and McGirr 1954)

None of these cases of sporadic non endemic goitrous cretinism has been due to deficiency of iodine or to the ingestion of goitrogens Obviously in all of them the hypothyroid state was due, not to a simple lack of thyroid tissue (as it is in the common sporadic non-goitrous cretin), but to an inability on the part of the thyroid gland to meet the body's requirements, even after considerable enlargement of the gland, most probably as the result of stimulation by thyrotrophin produced by the pituitary gland in response to a hypothyroid state

Our understanding of the pathogenesis of goitrous cretinism has been greatly furthered by the use of radioactive iodine (^{131}I) Excessive avidity of the thyroid gland for iodine has been a constant feature of these cases, but evidence has also accumulated which suggests a block in the synthesis of the thyroid hormone Discrepancies between the findings of different workers indicate that the block is not always at the same stage in every case It seems likely that this block is due to enzyme deficiencies at different levels of synthesis in different cases

The high prevalence of goitrous cretinism in the families of our patients led us to postulate that the condition may be due to an inborn error of metabolism (Hutchison and McGirr 1954) A similar opinion has been expressed by Wilkins et al (1954) and Childs (1954)

We have since been able to add considerably to the family tree of our largest family group (cases 1–7 and 13 of Hutchison and McGirr 1954) and to correct some of the inaccuracies previously reported to us The fuller details of this remarkable family seem worthy of record

Y-McX Family Group

Such details of the family tree as have been discovered are shown in the accompanying figure The members of this family group are itinerant tinkers living in Kintyre, Argyll, and the Isle of Islay, Scotland From time to time they travel in other parts of Scotland, and very probably other members of the family group are scattered throughout the country, although we have not found it possible to trace any with certainty These people are always on the move and this fact, combined with the distance from Glasgow of their usual haunts, explains our difficulty in collecting accurate data Even now we have reasons (see below) to believe that the family tree given here by no means exhausts the ramifications of the Y McX genes throughout Scotland

The original male Y came from Ireland to Scotland about 160 years ago and settled as a blacksmith at Southend Kintyre He married a McX, his full cousin A female Y (II 3) married another McX, who was her full cousin We have not been able to obtain a satisfactory pedigree of the main McX family, which is probably scattered widely throughout the West and North of Scotland So far as we know, none of the marriages in generation I of the Y family was consanguineous but in generations II and III the amount of intermarriage has been astonishing, and possibly largely brought about by the increasing demarcation and isolation of these people by the rapidly widening gulf between their mode of existence and that of the other inhabitants of the country

The family tree (see figure) shows that 10 known goitrous cretins (III 13, 21–23, and IV 9 and 10 and 16–19) have appeared among 31 persons in four lots of siblings (III 13–20, III 21–27, IV 9–15, and IV 16–24) 6 females and 4 males—an approximately equal sex distribution The results of radioactive iodine studies in 8 of these have already been published (cases 1–7 and 13 of Hutchison and McGirr 1954) The 9th cretin (III 21) is the elder sister of III 22 and III 23 (cases 7 and 6 of Hutchison and McGirr 1954) One of us has examined her clinically in Kintyre but she has not yet been submitted to detailed study The 10th (IV 10) is the younger brother of IV 9 (case 5 of Hutchison and McGirr 1954) and was first seen at the age of 4 weeks as a goitrous infant without signs of hypothyroidism Such signs have recently appeared at the age of 2 years The result of ^{131}I studies on this child suggests that the goitrous cretinism in this family is due to a deficiency of the enzyme dehalogenase (McGirr and Hutchison 1956)

There have also been 4 cases of Werdnig Hoffmann paralysis (IV 1–4) in another lot of siblings 3 patients died after hospital investigations in Glasgow and Edinburgh had established the diagnosis beyond reasonable doubt The 4th case (IV 4) has recently been diagnosed None of the parents of the cretins or of the patients with Werdnig-Hoffmann paralysis showed any evidence of disease We have personally seen all these parents We have not, however, examined all the supposedly healthy siblings of the cretins

Discussion

It is obvious from the high familial prevalence of sporadic goitrous cretinism noted by ourselves and others in the United Kingdom and in the United States that this form of hypothyroidism must be genetically determined In none of the present cases was there anything to suggest iodine deficiency or the ingestion of goitrogenic substances Endemic cretinism usually appears in the family of a mother who is goitrous from iodine deficiency, whereas in the present cases the parents were, without exception, healthy

It is therefore most unlikely that the appearance of goitrous cretinism in the Y McX family group is related directly to their common environment On the other hand, the pedigree (see figure) satisfies three of the unsuccessfully used extermination measures for fifty years at very great cost in value of herds of cattle and flocks of poultry, to get rid of swine fever, foot and mouth disease, and fowl pest, but it has learnt little or nothing of cure of these conditions though smallpox, cholera, typhoid, plague, and tuberculosis have largely been eradicated without the aid of unprofitable destruction of this type While the spectacle of numerous rabbits dying of the disease along every road horrified the public the spread of the disease was regarded as despicable and talks of punishment of the ill doers even mentioned, now we learn from the press notices that the Government seek the result at vast expense

Since it is admitted by all good farmers that "rabbits are a sign of bad husbandry, bad estate management, and bad government," and that there is land which cannot be profitably used in any better way than for rabbits, why use such infectious measures, the ultimate effect of which cannot be determined? Land will only yield a certain quantity of food for animals, and as long as farmers have not the means to use it profitably let us be thankful for the rabbit rather than seek a barren wilderness

Birmingham JAMES T BRAILSFORD

ABDUCTOR PARALYSIS AT THE SHOULDER

SIR,—May one offer a short congratulatory note to Mr Sharrard and Dr Knowelden on the clarity and usefulness of their paper last week It became apparent many years ago that to splint the shoulder in abduction was somewhat of a negation of common sense Paralysed or weak muscles need protection against the over action of opponent muscles and "over stretching" Neither of these deleterious factors apply to the shoulder abductors merely because the arm is kept in the natural position at the side of the trunk Therefore, to abduct is not required

I have not splinted the shoulder in abduction for simple paralysis for some fifteen years, and have never regretted it This paper, by the size of its sample—359 cases—and its method of control, provides the proof of my beliefs which my small series could not supply

Manchester W SAYLE CREER

ELECTRON-MICROSCOPY OF ATHEROMA

SIR—The statement by Dr Keech and Dr Reed (Dec 31) that the fibres I depicted (Dec 10) are reticulin is, I think, a little far fetched They claim to see an accentuation of every third component in the banding, But a careful scrutiny of figs 5 and 8 will show that such accentuations as are seen do not occur consistently at every third component, and can hardly therefore be regarded as significant They make the arbitrary statement that the aortic intima consists of, besides elastic tissue and amorphous material, fibres 300–900Å in width, but if they will look at my figures 5, 7 and 8 they will see fibres of no more than 100Å in width My so-called failure to mention elastic tissue was, of course, because I had carefully excluded from my preparations all but the superficial layers of the intima

My work was designed either to confirm or to refute Professor Duguid's prediction that much of the substance of an atheromatous plaque would show the characters of fibrin, and I think I succeeded in confirming it, but I carefully refrained in the main body of my paper from applying the term fibrin, and I think that Dr Keech and Dr Reed are bold in applying the term reticulin It would be interesting to know by what reasoning they relate the material I obtained from a mass of very dense fibrous tissue to reticular tissue Incidentally I would like to know how Dr van den Hooff (Dec 31) is able to identify as collagen, fibres which do not conform to the recognised electron-microscopic appearance of collagen

DOMICILIARY CONSULTATION IN PSYCHIATRIC PRACTICE

SIR,—Dr Philip Hopkins's letter (Dec 31) contains informative statistics on psychiatric patients in general practice Do I understand correctly from the table that none of the five patients diagnosed as schizophrenic were admitted to hospital? If so, further information about the clinical features and course of their illnesses, and of the action taken to help them, would be of interest

Warneford Hospital,
Oxford

IAN SKOTTOWE

*** This letter has been shown to Dr Hopkins, whose reply follows—ED L

SIR,—Dr Skottowe understands correctly that none of the five patients shown in the table accompanying my letter as diagnosed schizophrenic were admitted to hospital at the time of referral They were all referred to a psychiatrist, with whom rested the final diagnosis and the decision whether or not to admit them to hospital

CASE 1—A 26 year-old man consulted me on June 25, 1951, stating "I was with a girl friend last night and I suddenly had a terrible desire to kill her" In addition to this there had been feelings of unreality over the previous few weeks I had known him previously as a rather quiet withdrawn man Referral to a psychiatrist resulted in the diagnosis of schizophrenia, but while arrangements were being made for his admission to hospital he was arrested on a charge of repeated thefts over the previous few months and ultimately he went to prison for three months The magistrate was not influenced by the psychiatric report

CASE 2—On Sept 26, 1951, a 30 year old single woman came to me with a request to be referred to a plastic surgeon She stated that her nose had been getting bigger for some years and was now interfering with her appearance so much that people were talking about her She had, she said, previously had plastic operations on her nose in Cairo but the surgeon had made a terrible mistake She was plainly suffering from delusions and had been unable to work for some time I suggested that a psychiatrist could perhaps help her, and she agreed to go provided that she did not have to go into "an asylum" The psychiatrist's diagnosis was schizophrenia and he suggested that she should be admitted to a hospital for nervous disorders Neither the psychiatrist nor I have seen her since

CASE 3—A 31-year old single woman came asking to be referred back to a clinic she had attended eleven years earlier At that time there had been delusions mainly associated with men in her bedroom at night, a previous doctor had referred her to a gynæcologist to re-assure her that she was still a virgin and was not pregnant—but despite the reassurance she still insisted she was pregnant Following individual psychotherapy she had been able to continue with her work as a teacher, but her symptoms were worse when she consulted me on March 16 1953 I referred her back to the clinic as she requested, but before she could resume treatment as suggested she took a job as a teacher abroad. I have recently been told by this patient's mother that she is still working, but lives "a very secluded life"

CASE 4—On July 13 1953 a single man, aged 30, asked for a "tonic"—but after a lengthy interview he agreed to go to a psychiatric clinic I had been seeing him from time to time for the previous twelve months for "supportive" therapy, as he was clearly a chronic schizophrenic he had been brought up in a foundlings' hospital, had never known his parents, and had no friends At $14^1/_2$ years of age, he had been placed in the Regular Army as a band boy, after nine years he took his discharge, since when he had wandered from job to job He had been afraid to mix with people as he thought they talked and laughed about him, he always felt inferior and had become completely withdrawn I referred him for psychiatric assessment, as a result of which it was agreed that I should continue to see him for "supportive" therapy He managed fairly well by this means for some months, but eventually he left London, and I saw him no more

CASE 5—On Dec 12, 1953, a 25 year-old single man consulted me with a number of symptoms, I had seen him many times during the previous three years on account of [illegible] symptoms, mostly associated with anxiety He lived with his parents, with whom he had never got on well [illegible] no friends and tended to be withdrawn He wanted to paint, but although talented he could not keep any job for long as he was unable to concentrate and could not get on well with his employers or those he worked with He had feelings of inferiority, lacked self confidence, and was unable to sleep I thought he was worse than usual and referred him for psychiatric assessment He was at first thought to be suffering from a severe anxiety neurosis and was put on the waiting list for psychotherapy It was some time before this was started, and after about four months in treatment (weekly sessions for individual therapy) his therapist concluded that the diagnosis was schizophrenia Admission to hospital for insulin therapy was arranged, and after five months he was discharged considerably improved A month later, however, I had to have him readmitted by the duly authorised officer when he had an acute schizophrenic breakdown in which he attacked his father and broke up the furniture and fittings in his parents' home He was discharged in November, 1955, and is now attending a day hospital, where he is reported as doing fairly well but the report on his behaviour for December, 1955, states "He is painting well and plans to teach art, but he still wanders aimlessly and is unable to concentrate"

Unlike the consultant, the general practitioner cannot say to his patient that he can do nothing for him, the patient has no one else to help him, and only too often it is left to the general practitioner to think up some way in which to help even the most difficult chronic patient—with untreatable psychosis or inoperable cancer

It is only the schizophrenic in an acute episode or the certifiable chronic who is admitted to mental hospital—for treatment or custody When the mental hospital specialist's enthusiasm has waned, or when the patient refuses to stay longer in hospital, he is sent home as untreatable Nevertheless, it is surprising how some of these chronic schizophrenic patients can be kept usefully employed with occasional interviews for supportive therapy Watts[1] has described well the types of patient that the general practitioner may be called on to look after, and he rightly points out that if it is possible to keep them at home it is often better for the patient, and more economical for the country, to do so This is the type of case where often the day hospital, as described by Bierer,[2] can be of value, for again it is cheaper to keep the patient in a day hospital than as an inpatient in a mental hospital

On the other hand, if Dr Shottowe has any alternative methods he can recommend for the care of these often very difficult and trying patients I will be extremely pleased to know them—for there is very little help to be gained from the standard textbooks on psychiatry

London, N W 3 PHILIP HOPKINS

CONSULTANTS IN DERMATOLOGY

SIR,—Dr Franklin's generalisation (Dec 31), based apparently on his experience of one venereal diseases clinic, that the care of venereal diseases clinics may be safely relegated to dermatologists does not in the least alter my view, based on knowledge of the work of all the V D clinics in this country, that, so far as this country is concerned, such relegation would be a retrograde step

Dr Franklin's remark that "the work of the V D clinic can be readily learnt by any competent consultant" reminds me of an incident in the 1914–18 war, when I was adviser in V D to the War Office

The D M S of a certain Command, without reference to others, suddenly posted the pathologist of an important V D section of a military general hospital for service oversea, leaving that section without anyone capable of doing the V D pathology there The result was a moan from the commanding officer of the general hospital, which produced a "raspberry" from the D M S for the C O not having had an understudy available to take the pathologist's place, and an order to "detail a medical officer to proceed to the Military Hospital, Rochester Row, for a few days to learn the Wassermann test" The original pathologist, by W O direction, was back in his laboratory within a week of his havin been sent oversea The O C the general hospital, about th same time, received an order from his D M S that in futur all communications with the O C, Military Hospital, Rochest Row, must be "sent through this office"

London, S W 1 L W HARRISON

EXPELLING TAPEWORMS WITH MEPACRINE

SIR,—The rewards from oral treatment of tapeworm infestation with mepacrine have been so constant tha courage is rising to leave out some of the ritual hangin on from the old régime with male fern When drivin out a worm lying in the jejunum, is it not enough t make sure that there is no fæcal block to its passage And can sodium bicarbonate, except possibly in th achlorhydric, do anything to mucus round the worm scolex ?

A boy, aged 4, had a diet of fluids only (with glucose) and 'Milk of Magnesia' ½ oz morning and evening on Dec On Dec 28 he swallowed 500 mg of mepacrine at 6 A M, washing down each tablet with a sip of water At 7 A M h took *milk of magnesia* ½ oz, and at 9 A M he was given a soap and water enema By 9 50 A M he had passed th scolex He did not vomit till 9 40 A M, after a drink of milky tea By 2 P M he could manage chicken and milk

Till a tastier drug arrives, it is worth while bearing the bitterness of mepacrine, but has not the time come to wonder what the starving and bicarbonate are for ?

SPORADIC CRETINISM WITH GOITRE

SIR,—Your annotation of Dec 24 prompts us to comment on two recent publications by Stanbury and hi colleagues,[1 2] and to present additional information about a child of the tinker family previously described by us[3 4]

The evidence suggests that there are at least *three* distinct biochemical defects in thyroid-hormone synthesis —not two, as you state

Firstly, there may occur an inability to incorporate inorganic iodide into an organic iodine containing compound[5 6]

Secondly, there may be an impaired ability to couple two molecules of di iodotyrosine to yield thyroxine[1] In the patient in whom this defect was found, Stanbury and his colleagues did not (as you state) identify mono and di iodo tyrosine in the peripheral blood, but they did find tri iodo thyronine and thyroxine In the thyroid gland, however, *mono and di iodotyrosine were present in very large amounts* but thyroxine was detected only with the greatest difficulty

Thirdly, there may be an inability to conserve the iodine of the iodotyrosyl groups owing to deficiency of the enzyme dehalogenase, which normally acts within the thyroid gland by de iodinating these groups and so prevents their loss from the gland It was in the serum of the patient in whom this defect was found that Stanbury et al[2] identified mono and di iodotyrosine as well as thyroxine and tri iodothyronine This was the first time that the spontaneous occurrence of di-iodotyrosine in the peripheral blood was conclusively proved It seems likely, as you say, that the patients studied earlier by Hubble[7] and ourselves[3 4] may belong to this third group

During the past two weeks we have been investigating with radioactive iodine an *additional member* of our large tinker family

He was first seen two *years ago, at the age of 4 weeks* when it was noted that he was goitrous but euthyroid He has now been admitted to hospital because signs of hypo-

criteria usually accepted as indicating simple recessive inheritance (Roberts 1940)

(1) The parents of the affected persons are normal to outward appearances
(2) There is a striking familial prevalence three of the four lots of siblings contain more than one affected child The ratio of normal to affected persons (21 10) shows the usual excess over the 3 1 ratio which is typical of recessive inheritance because we have adequate information only about sets of siblings in whom at least one person is affected A number of normals in unaffected sibships must be unknown to us
(3) All the affected persons are the children of consanguineous marriages

Other characteristic, but rarely encountered, criteria of autosomal recessive inheritance are as follows

(4) Affected persons who marry normals will have only normal offspring in most instances
(5) Affected persons who marry affected persons will have affected offspring only

These last two criteria have not been satisfied in the present pedigree, but in view of the predilection for consanguineous mating it is not inconceivable that the thyroid treatment instituted by us may alter this position in time

Though it may properly be claimed that simple recessive inheritance cannot be proved on the strength of a single pedigree, the occurrence of familial prevalence and consanguinity in the families of other similar cases which we have cited makes it extremely probable that the present cases were so determined The appearance within the same pedigree of Werdnig-Hoffmann paralysis—a disease known to be inherited as a mendelian recessive (Gates 1946)—is interesting Here also the first three criteria of recessive inheritance mentioned above are fulfilled

We have alluded to the possibility that the gene producing goitrous cretinism in the Y-McX family may be operating elsewhere in Scotland We have already recorded the appearance of 3 siblings with goitrous cretinism in another family (Hutchison and McGirr 1954) These also were tinkers They were referred to us by Prof J L Henderson, of Dundee Careful inquiry by Professor Henderson failed to produce any evidence that they were related to the Y McX cretins, but (like us) he met some resistance in taking a family history from these people We have recently had the opportunity of applying radio-iodine tests to 2 more cretinous siblings with goitre, who were referred to us by the Renfrewshire local authority from a home for deprived children They gave results which were identical with those found in our earlier cases The parents of these 2 children were also itinerant tinkers but could not now be traced In view of the unique and self demarcated mode of life of tinkers, who tend to intermarry and to live a life apart from the rest of the community, it seems at least probable that the various cretinous siblings whom we have studied owe their condition to the same recessive gene occurring in the homozygous state.

Summary

The pedigree of a group of itinerant tinkers is presented It is noteworthy for the remarkable frequency of consanguineous mating

Within this family group there were 10 cases of goitrous cretinism and 4 cases of Werdnig Hoffmann paralysis

Goitrous cretinism and Werdnig Hoffmann paralysis are each due to the effect of single but quite separate autosomal recessive genes

We wish to thank Dr Catherine A Brown, executive school medical officer, Argyll County Council, for her great help in tracing the various members of the family group, and Professor Henderson for his efforts to find the connecting link between his cretinous tinkers and ours

VASOPRESSIN TANNATE IN OIL AND THE URINE CONCENTRATION TEST

H E DE WARDENER
M B E , M D Lond , M R C P
SENIOR LECTURER IN MEDICINE,
ST THOMAS'S HOSPITAL MEDICAL SCHOOL, LONDON

THE maximal ability of the kidney to concentrate the urine is generally considered to be a good indication of renal function, but to approach this concentration, at least twenty-four hours' deprivation of fluid is necessary (Miles et al 1954) Deprivation of fluid, however, is seldom strictly controlled and depends on the variable amounts of water in the food and on the vigilance of the nurses For the patient the test is nearly always unpleasant and occasionally, if a severe negative fluid-balance develops, it may be hazardous The patient's emotional reaction to being deprived of fluid may also cause the results to be quite misleading (Miles and de Wardener 1953) Furthermore, because of its unpleasantness and potential danger, the concentration test is nearly always performed on only one occasion, although its value would be much increased if it were repeated This natural disinclination to repeat the test is probably its greatest disadvantage

To avoid these disadvantages Miles et al (1954) investigated the possibility of substituting an injection of vasopressin tannate in oil for a long period of fluid deprivation The concentration of the urine after deprivation of fluid was compared in the same subjects with that obtained after the intramuscular injection of 5 units of vasopressin tannate in oil In 10 subjects convalescing from non renal diseases the concentration of the urine after deprivation of fluid was usually greater than after the injection of vasopressin , the discrepancy in 3 of them being substantial , in 9 subjects with renal disease there did not appear to be any difference between the two methods It was considered from these few results that vasopressin tannate was unlikely to be a sufficiently reliable substitute for deprivation of fluid in testing the kidney's maximal ability to concentrate the urine Since these findings were reported, however, the same experiment has been extended to 43 more subjects, of whom 17 were normal (Jones and de Wardener 1956) and 26 were patients, of whom 18 had renal disease and 8 were convalescent from non renal disease The collected results from all these 62 subjects are given below , they confirm that the concentration of urine after deprivation of fluid is greater than after the injection of vasopressin, but they also show that the difference is such that for

RUPTURE OF INTRA-ABDOMINAL ANEURYSM SIMULATING RENAL COLIC

R C King
M D Lond, M R C P
SENIOR MEDICAL REGISTRAR

J O Robinson
M A, M Chir Camb, F R C S
SENIOR SURGICAL REGISTRAR

ST BARTHOLOMEW'S HOSPITAL LONDON

The symptoms referable to aneurysm of the abdominal aorta were analysed by Osler (1905), who stated that the pain due to rupture may resemble the pain of renal colic, gall stones, or appendicitis He cited a case (Bryant 1903) which presented with pain similar to that of renal calculus, agonising in severity and radiating into the left groin and testis Since then the frequency of aneurysm of the abdominal aorta has increased (Zech and Merendino 1954), and the proportion of arteriosclerotic to syphilitic aneurysms has been reversed Osler (1905) gave a ratio of 1 10 whereas Maniglia and Gregory (1952) found the proportion to be 5 2

This relative and absolute increase in the frequency of arteriosclerotic aneurysms has an important bearing on the symptoms Syphilitic aneurysms commonly erode the vertebræ, whereas arteriosclerotic aneurysms rarely do so, as a result pain is an early symptom in the former but comes on much later and less often in the latter Blakemore (1947) has pointed out that arteriosclerotic patients may in fact go to the brink of disaster before experiencing symptoms, and that the first symptom is often pain due to leakage from, or rupture of, the aneurysm

Recent advances in anæsthetic and surgical techniques have made the treatment of abdominal aneurysms a practical proposition, arteriosclerotic aneurysms are particularly amenable to treatment as they often arise distal to the origin of the renal arteries Blakemore (1947) produced satisfactory results in 3 patients with arteriosclerotic aneurysms employing a process of electrothermic coagulation, and Kinmonth et al (1955) have successfully substituted a tube of 'Orlon' cloth for a large abdominal aneurysm The fact that a condition which may be rapidly fatal can now be successfully treated makes early diagnosis imperative

We report here 2 cases of fatal rupture of arteriosclerotic intra-abdominal aneurysms, both of which presented with severe abdominal pain indistinguishable from that of renal colic

Case-reports

Case 1—An engineer, aged 62, had been well until the day before admission to hospital While travelling on a train in Germany he suddenly experienced severe pain in the left loin It lasted only a few seconds but was accompanied by a feeling of faintness The journey to England was continued without further incident, but shortly after leaving Liverpool Street Station next day the pain recurred with such agonising intensity that he lost consciousness He was admitted to St Bartholomew's Hospital as an acute abdominal emergency There was no relevant past or family history

On examination he had recovered consciousness but was still shocked, with pulse rate 58, pulse regular, temperature 95°F, respirations 30 a minute, and blood pressure 90/35 mm Hg He was obese, his pupils reacted to light and accommodation, and the fundi showed narrowed arterioles with arteriovenous nipping There was tenderness in the left loin with guarding Bowel sounds were normal

Investigations—Examination of the blood showed Hb 68%, white cells 13,700 per c mm (polymorphs 90% lymphocytes 8%, monocytes 2%), erythrocyte sedimentation rate 12 mm in the first hour (Westergren) The urine contained a trace of protein but no blood, the blood urea level was 80 mg per 100 ml Plain radiography of the abdomen showed no gaseous distension, subdiaphragmatic air, or renal calculi Electrocardiography showed left ventricular hypertrophy with patchy myocardial ischæmia

Course—An hour after admission the patient felt better, his blood pressure had risen to 160/80 mm Hg and pulse rate to 100 Three quarters of an hour later he had an attack resembling typical renal colic, which consisted of severe pain in the left loin radiating into the left groin and penis His blood-presure fell, but he did not lose consciousness Atropine sulphate gr $^1/_{100}$ was given subcutaneously, and the pain subsided Three and a half hours later he again collapsed, his blood pressure falling to 95/40 mm Hg, but on this occasion there was no pain For the next twelve hours, throughout the night, he remained shocked but pain free Next morning a definite pulsatile mass was palpable in his left loin

Exploratory laparotomy was performed by Mr John Hosford, who found that a large aneurysm of the abdominal aorta had ruptured into the retroperitoneal tissues No treatment was possible, and the patient died thirty one hours after admission and sixty one hours after the onset of the first symptom

Necropsy revealed widespread atherosclerosis affecting especially the coronary vessels and the abdominal aorta There was marked left ventricular hypertrophy, the kidneys appeared normal, and there were no calculi in the urinary tract Immediately distal to the origin of the renal arteries the abdominal aorta had a large fusiform aneurysmal dilatation with additional sacculation to the right, the maximal circumference being 19 cm The left lateral wall of the abdominal aorta 3 cm above the bifurcation had an irregular tear 2 5 cm long The rupture communicated with a retroperitoneal hæmatoma which surrounded the left kidney and ureter and extended into the soft tissues of the pelvis on the left side Sections of the abdominal aorta showed extensive atheromatous lesions

Case 2—A cable operator, aged 55, had been a known hypertensive for five years with a blood pressure of 240/140 mm Hg, and two years before admission he had had an isolated episode of hæmaturia On the morning of the day of admission he developed, following defæcation, an aching right sided abdominal pain which radiated into the right testis The pain subsided after a few minutes but recurred momentarily with much greater intensity in the afternoon This second attack of pain was succeeded by a desire to defæcate again, but before he could do this he lost consciousness He was admitted to St Bartholomew's Hospital as an acute abdominal emergency half an hour later When first seen his complaint was of severe pain in the right testis and an aching pain in the right iliac fossa and groin There was no other relevant past or family history

On examination he was obese, shocked, and in severe pain, with temperature 95°F, pulse rate 114, pulse regular, respirations 22 a minute and blood pressure 65/50 mm Hg His pupils reacted to light and accommodation, and his fundi showed narrowed arterioles with arteriovenous nipping He had diffuse lower abdominal tenderness with guarding on the right side and severe tenderness in the right groin Bowel sounds were present, and the external genitalia were normal The right testis was not retracted but the right cremasteric reflex was absent The femoral pulses were palpable and equal clinical purposes, it seems justifiable to substitute vasopressin tannate in oil for a long period of deprivation of fluid.

Methods

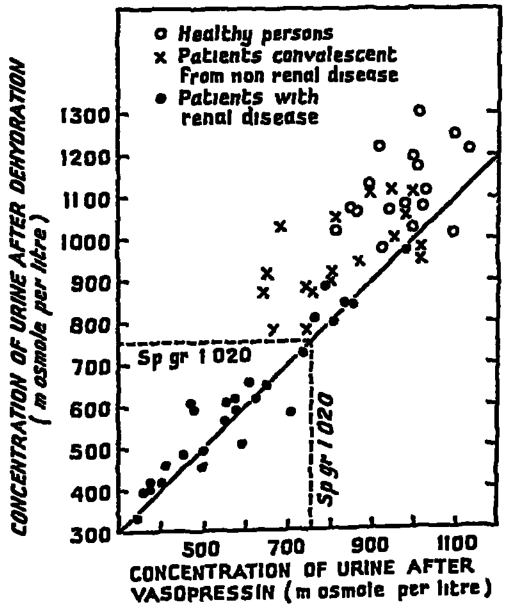
Deprivation of fluid was for thirty-six hours from 8 A.M., except the 17 healthy subjects, who were deprived of fluid for forty-eight hours from 8 P.M. During this time soups, ice cream, and fruit were also withheld. The urine tested was that passed during the last eight hours of the period of deprivation—i.e., from noon to 8 P.M.

The effect of injecting vasopressin was observed one to two weeks after the fluid-deprivation test. Vasopressin tannate 5 units in oil was administered subcutaneously at 7 A.M., and the urine tested was that passed between noon and 8 P.M. on the same day. During this day all the subjects tested were allowed to eat and drink what they wished, but in addition the 17 healthy subjects were given 1000 ml. of water an hour after the injection of vasopressin for reasons already published (Jones and de Wardener 1956).

The osmolar concentration of the urine was calculated from the depression of its freezing-point. A mercury thermometer was used in the 19 original cases (Miles et al. 1954) and a thermistor in the remainder (de Wardener and del Greco 1955). The standard deviation of a reading with the thermistor is ±0.0102°C, corresponding to ±5.5 milli-osmole per litre.

Results

The results are illustrated in the accompanying figure, which shows the osmolarity of the urine after deprivation of fluid plotted against the osmolarity after an injection of vasopressin tannate in oil in 62 subjects. The scale of the abscissa is the same as that of the ordinate so that the line drawn at 45° to the abscissa represents the line along which the points would lie if the concentration of the urine after deprivation of fluid were the same as that after the injection of vasopressin. It can be seen, however, that the results have a linear relationship which lies slightly above this line, indicating that the concentration of the urine following deprivation of fluid is greater than after the injection of vasopressin. It is also evident that this difference becomes less as the osmolarity of the urine approaches that of plasma (about 300 milli-osmole per litre).



Osmolarity of urine after 36–48 hours deprivation of fluid compared with that following injection of vasopressin tannate in oil in 62 persons. diagonal line shows where points would lie if deprivation of fluid and vasopressin tannate concentrated urine equally.

Discussion

The concentration of the urine is greater after fluid deprivation than following an injection of vasopressin tannate in oil, but this difference only amounts, in terms of specific gravity, to approximately 0.002 at a specific gravity of 1.022, and becomes less at lower urine concentrations. (The correlation between specific gravity and osmolarity of the urine has been obtained from the data of Miles et al. [1954].) It therefore seems justifiable, in testing the kidney's ability to concentrate the urine maximally, to substitute an injection of vasopressin tannate in oil for a long period of deprivation of fluid.

The reproducibility of this method is satisfactory. When vasopressin was given on three occasions to each of 9 healthy persons, the standard deviation of an estimate of the greatest concentration of the urine was 82 milli-osmole per litre (in urine 33 milli-osmole per litre is approximately equivalent to sp. gr. 0.001). Comparable figures for repeated deprivation of fluid were available in only 3 healthy persons each of whom was tested on two occasions, so that a proper comparison is impossible; it can only be stated that the greatest difference found in any one person was 46 milli-osmole per litre.

In the observations reported here the urine had to be collected at controlled intervals so that the comparison between the two techniques should not be confused by diurnal changes; but, since the effect of 5 units of vasopressin tannate in oil on the concentration of the urine continues for at least twenty-four hours, there is no need to do this for routine purposes. It is only necessary to measure the specific gravity of all samples of urine passed during the twenty-four hours following the injection of vasopressin tannate.

The one serious disadvantage of the use of vasopressin tannate in oil is that the vasopressin tannate is in suspension. When it has been standing the vasopressin collects as an insignificant brown discoloration at the bottom of the ampoule, and it is necessary to warm and shake the ampoule vigorously before use. It is also an advantage to use a large-bore needle to transfer the oil and vasopressin from the ampoule to the syringe.

There have been no complications following the administration of vasopressin tannate in oil except a feeling of torpor in the 17 healthy persons, who were also given 1000 ml. of water. This symptom did not develop in patients who drank only what and when they wished. Finally, freedom from side-effects and the greater convenience of the test when done with vasopressin allow the test to be repeated fairly frequently (weekly), thus greatly increasing its value.

Summary

The concentration of urine after deprivation of fluid has been compared with that following an injection of vasopressin tannate in oil in 17 healthy subjects, 18 patients convalescent from non-renal disease, and 27 patients with renal disease.

The concentration of the urine after deprivation of fluid was slightly greater than after the injection of vasopressin. This difference was least noticeable when the specific gravity of the urine was less than 1.020.

It is suggested that when an estimate of the kidney's maximal ability to concentrate urine is required for clinical purposes, an injection of vasopressin tannate in oil can be justifiably substituted for a long period of fluid deprivation.

Investigations—The urine contained a trace of protein but no blood the blood urea level was 80 mg per 100 ml, serum amylase 6 Wohlgemuth units, and plain radiography of the abdomen revealed gall stones

Diagnosis—Torsion of the testis was excluded by the normal appearance of the testes Severe renal colic was thought to be the next most likely diagnosis, but acute pancreatitis, perforated peptic ulcer, and coronary thrombosis were considered in the differential diagnosis It was suggested by one of us that "dilatation of, or leakage from, the abdominal aorta or a peripheral (intra abdominal) artery, such as the renal artery, would explain the picture," but this opinion was not held sufficiently strongly to lead to laparotomy

Course—The severe pain subsided in thirty minutes, but a dull ache in the right loin and groin remained The blood-pressure rose to 120/80 mm Hg No new physical signs appeared, but over the course of the next three days there were transitory attacks of pain which radiated from the right loin to the groin The pain appeared to be relieved by subcutaneous atropine sulphate Despite an adequate fluid intake the output of urine decreased and the blood urea level rose to 180 mg per 100 ml On the third day the patient again collapsed with severe pain in the right loin and groin, and he died an hour later—ninety two hours after the appearance of his first symptom

Necropsy revealed gross left ventricular hypertrophy The gall bladder contained gall stones, but the kidneys were macroscopically normal, and there were no calculi in the urinary tract The aorta showed a little atheroma, mainly in the abdominal region, and there was a saccular aneurysm 2 5 cm in diameter in the lateral wall of the right common iliac artery 4 cm from its origin There was a linear rupture 1 cm long in the wall of the aneurysm The adventitia had been dissected from the media over an area extending 3 cm from the tear, the gap between the two layers containing blood clot In continuity with the tear there was a large retroperitoneal hæmatoma filling the right iliac fossa and right half of the pelvis and extending superiorly as far as the perirenal area Section of the kidneys showed benign hyper tensive disease, and the aorta showed moderate atheromatous changes in the intima, but the wall of the aneurysm showed no evidence of arteriosclerosis or syphilis

Discussion

Arteriosclerotic aneurysms develop almost exclusively after middle age Of 97 patients with such lesions reported by Estes (1950) all were aged more than 40, and about 70% were aged more than 60 Rupture of or leakage from such an aneurysm may never occur, the condition remaining undiscovered until necropsy, alternatively it may give rise to symptoms which lead to its being diagnosed before it ruptures

Of Blakemore's (1947) 26 patients 5 presented with a pulsatile abdominal mass 1 with pain resembling that of duodenal ulcer, and 1 with symptoms referable to duodenal ileus and obstruction

Only 4 of 15 patients described by Scott (1944) had symptoms—in each case aching pain in the lower abdomen and back

More rarely symptoms may result from pressure on other intra abdominal organs, but very much less frequently than is the case with syphilitic abdominal aneurysms An aneurysm may rupture silently, leading to rapid death, or into the gastro intestinal tract, most frequently the duodenum, producing hæmatemesis and/or melæna

Rupture is often preceded by a leak, in which case the patient may present with severe pain as an acute abdominal emergency

Of Blakemore's (1947) 26 patients 11 presented with severe pain heralding rupture

Of 61 cases reported by Zech and Merendino (1954) in 24 severe pain came on before rupture and in 7 laparotomy was undertaken for what were thought to be acute abdominal emergencies The preoperative diagnoses were perforated peptic ulcer (4), urinary retention (1), pancreatitis (1) and volvulus (1)

Of the patients reported by Hubeny and Pollack (1940) 2 presented with acute pain preceding rupture, and both were diagnosed as having a perforated peptic ulcer Whether these cases were syphilitic or arteriosclerotic is not stated

Of great importance is the time which may elapse between the onset of the first pain due to the initial leak and death from rupture In Estes's (1930) series were 6 patients who survived ten hours, five days, four weeks four weeks, six months, and four years respectively after the first leak In 8 of the cases reported by Zech and Merendino (1954) small leaks had sealed before the aneurysm ultimately ruptured In the 2 present cases the intervals between the first pain and death from rupture were sixty-one and ninety-two hours It is during this period that surgical treatment might be attempted

It is not clear why the pain resembled renal colic in the present cases It is unlikely that it was due to sudden dilatation of a blood vessel, but the dissection of the iliac artery in case 2 might explain the initial severe pain It is possible but improbable that the presence of blood clot surrounding the ureter on the affected side in each case caused ureteric spasm and pain It seems more likely that the pain was due to leaking blood dissecting the retroperitoneal fascial planes and muscles of the first and second lumbar segments, for Kellgren (1937) has shown how pain resembling that of renal colic may be produced by injecting saline solution into the interspinous ligaments and muscles of the first lumbar segment

There were two striking clinical features seen in both patients the extreme degree of shock, which was comparable to that seen in association with myocardial infarction, and the relative speed with which the severe pain disappeared The absence of firm evidence of other intra-abdominal conditions which could cause the symptoms might have led us to consider more seriously a vascular cause for the pain, particularly as both patients were aged more than 50 and had widespread signs of arteriosclerosis Case 2 had, however, had a previous episode of hæmaturia and also showed radio graphic evidence of gall stones, while the diagnosis of renal colic was supported in both cases by proteinuria and a raised blood urea level An interesting clinical point in case 2 was the absence of the right cremasteric reflex, probably resulting from pressure of blood clot on the right genitofemoral nerve

It would be unwise to generalise on the basis of these 2 cases, but the sudden occurrence, in an arteriosclerotic subject, of a relatively short lived but severe abdominal pain associated with severe shock should suggest the possibility of its being due to a leak from an intra abdominal aneurysm

Summary

The first symptom of an arteriosclerotic intra abdominal aneurysm may be severe abdominal pain of sudden onset, resulting from a leak and mimicking that of other acute abdominal emergencies

With the advent of new anæsthetic and surgical techniques treatment of such aneurysms is now practic able, and since an appreciable time may elapse between the onset of the first symptom due to a leak and death from rupture, early diagnosis is of paramount importance

An account is given of 2 fatal cases of ruptured intra abdominal aneurysm, both of which presented with severe pain resembling renal colic

We are grateful to Dr E R Cullinan and Mr John Hosford for permission to publish, and to Dr R Finlayson and Dr P J A Butcher for the necropsy reports

REGISTRAR IN PATHOLOGY

ROYAL INFIRMARY, BRISTOL

MOST cases of localised and generalised peritonitis are caused by organisms from the intestine The organisms usually incriminated in surgical textbooks are *Escherichia coli* and other members of the coliform group and aerobic streptococci Anaerobic streptococci and clostridia are sometimes mentioned, but the anaerobic non sporing bacilli of the Bacteroides group are usually ignored

The pioneer work of identifying these organisms was done by Continental bacteriologists

Loeffler (1884) observed *Bacteroides funduliformis* (*Bacillus necrophorus*) in calf diphtheria

Veillon and Zuber (1898) found them in appendicitis, and Halle (1898) in diseases of the female genital tract

Vincent (1896) found a fusiform bacillus of the same group in ulcerative *lesions of the throat*

Similar organisms were subsequently demonstrated in normal mouths (Tunnicliff 1906, Slanetz and Rettger 1933) and in the healthy alimentary canal (Eggerth and Gagnon 1933, Weiss and Rettger 1937)

Bacteroides are the predominant organisms in the lower intestine, where they greatly outnumber *Esch coli*

For some time after the early work on Bacteroides their role in the causation of human infections was largely neglected for several reasons the comparatively slow growth and the delicacy of Bacteroides compared with the other bacteria which often accompany them in pus and may overgrow them in cultures, the frequent omission of anaerobic methods from routine bacteriology, and, perhaps, the failure to ensure an adequate carbon-dioxide tension in anaerobic apparatus A deficiency of carbon dioxide may inhibit the growth of some strains (Lewis et al 1940)

More recently the importance of Bacteroides infections in many parts of the body has come to be more widely recognised

Weinberg et al (1928) found anaerobic gram negative rods, accompanied by many other organisms, in acute appendicitis Schmitz (1930) also found them numerous in appendicitis

Harris and Brown (1927) found Bacteroides in 6 patients with postpartum infections

Thompson and Beaver (1932) reported 2 cases of fatal bacteræmia and noted 10 others in the literature

Cohen (1932) isolated several species of Bacteroides from 16 lung abscesses

Lemierre (1936) described cases of Bacteroides septicæmia in which the infections spread from lesions of the mouth and jaw, the endometrium, the appendix, and other sites

Dixon and Deuterman (1937) reported 6 postoperative abdominal infections

Beigelman and Rantz (1949) reviewed 47 infections in 34 of which the Bacteroides were associated with other organisms

McVay and Sprunt (1952) observed 35 cases in five years, the infections involved the respiratory system, the gastro-intestinal tract the female genital and urinary tracts, and the skin

Clark and Wiersma (1952) and Carter et al (1953) reported infections originating in the female genital tract in 47 and 153 patients respectively

Alston (1955) reviews this subject and describes 12 cases due to *Bacteroides necrophorus*

There have not been many reports of the sensitivity of Bacteroides to antibiotics

Foley (1947) and Beigelman and Rantz (1949) found that Bacteroides were often resistant to penicillin and streptomycin

McVay and Sprunt (1952) tested a few strains with penicillin, streptomycin, sulphadiazine, and aureomycin and found aureomycin to be much the most effective

Fisher and McKusick (1953) found that strains varied greatly in sensitivity to penicillin and streptomycin, but most were highly resistant, all six strains tested with chloramphenicol and all seven with aureomycin were sensitive

Garrod (1955) describes the results of a thorough investigation of the sensitivity of four species of Bacteroides (55 strains in all) to seven antibiotics He found that all four were relatively resistant to streptomycin and sensitive to chloramphenicol and oxytetracycline Three of the four species were sensitive to penicillin

We report here a study of the bacteriology of intra-abdominal sepsis Our objects were to find how often Bacteroides were present compared with other organisms, and to determine the sensitivity of Bacteroides to antibiotics and sulphonamide We regarded all gram-negative anaerobic non sporing bacilli as Bacteroides, although this definition covers a heterogeneous group of organisms

Material and Methods

Most of the organisms were isolated from pus from suppurative lesions in the abdomen, sent to the laboratory for routine examination in the year from Sept 30, 1954, to Sept 29, 1955 There were 34 specimens from either localised or generalised peritonitis caused by appendicitis, 18 specimens from peritonitis of other causes, and 46 swabs from discharging wounds of the abdominal wall These 46 were selected for anaerobic study from 156 abdominal-wound swabs because the clinical features of the cases or study of the direct smears indicated the probability of anaerobic infection In several of these wounds the pus was forming inside the abdomen and discharging through a drainage tube or a fistula but in a few the infection was in the abdominal wall In addition, 13 acutely inflamed appendices were obtained from the operating-theatre as soon as possible after operation and were studied in more detail than was possible with specimens sent to the laboratory for routine examination

Smears and cultures were made from pus and from the peritoneal surfaces and walls of the appendices, care being taken to avoid contamination from their lumina Careful microscopy of gram-stained smears was found to be important Bacteroides were often clearly distinguishable from coliform bacilli, being more slender and shorter or, less often, filamentous or fusiform Aerobic cultures were made on MacConkey agar and on 5% horse-blood infusion agar plates Anaerobic cultures were made on blood-agar and were incubated in an atmosphere of hydrogen containing 5% carbon dioxide in McIntosh and Fildes (1916) jars All the cultures were examined after one day's and two days incubation at 37°C, and many of the anaerobic plates were incubated longer Organisms which grew only on the anaerobic plates were retested for anaerobiosis by subculturing them on aerobic and anaerobic blood-agar One or more subcultures were often required to separate the Bacteroides from the anaerobic cocci and other organisms accompanying them Strains were preserved for future examination by freeze-drying with an Edwards' centrifugal freeze dryer suspensions made in horse serum

Sensitivity of Bacteroides to Antibiotics and Sulphonamide

Sensitivity tests were put up on anaerobic blood-agar plates with penicillin, streptomycin, chloramphenicol, oxytetracycline, chlortetracycline tetracycline, erythromycin, bacitracin, neomycin, and polymyxin B For most of the tests a disc method was used (Fairbrother and Martyn 1951, Fairbrother and Jennings 1955) The sensitivity of a smaller number of strains was measured more exactly by a quantitative method in which doubling dilutions of the drugs were incorporated in the plates, the lowest concentration which much reduced the growth of the organisms after forty-eight hours' incubation was taken as the lowest inhibiting concentration As a control the Oxford staphylococcus, grown anaerobically, was included in each batch of strains tested with all the drugs

Reviews of Books

Atlas Illustrating the Topographical Anatomy of the Head, Neck and Trunk

The late Johnson Symington, M D F R C S, F R S, professor of anatomy, The Queen's University, Belfast Edinburgh Oliver & Boyd 1956 £5 5s

THIS atlas first appeared in 1917, and the plates and copyright were bequeathed to the Anatomical Society of Great Britain and Ireland by Professor Symington's daughter in 1932 In response to many requests, the council of the society has now decided to republish the atlas, using the original blocks The plates are life-sized half-tone drawings of a series of cross-sections taken at regular intervals through two male adult bodies, one serving for the trunk and the other for the head and neck The accompanying reconstructions show the levels of the sections in relation to the skeletal features The plates are printed on thick glossy paper and are stored in a stout and convenient portfolio The reproduction is good, and the main features of each section are adequately labelled, the whole atlas forms a justly renowned contribution to cross-sectional anatomy Since the pictures are life-size, direct measurements may be made on them from the surface to any desired structure, and experience has already shown their very great value to surgeons and radiologists A new generation of anatomists will also welcome the reappearance of this old friend of their seniors, for there can be no doubt of the usefulness of cross-sections in making the student revise his topographical knowledge

Nursing Care of the Newly Born Infant

W S Craig, M D F R C P, professor of pædiatrics and child health, University of Leeds In collaboration with M F G Buchanan, M R C P E, R J Pugh, M R C P, M Pattullo, R G N, S C M, and M J W Taylor, R G N S C M M T D Edinburgh E & S Livingstone 1955 Pp 472 35s

THIS is an excellent work which every midwife should read, and which every obstetrician should insist is kept in his department

Not long ago the newborn infant was often looked on as a by product of the art of obstetrics and obstetricians bothered very little about this side of their business Pædiatricians were "new fangled upstarts who were forbidden entry, so that the care of the infant fell to the midwife who wielded far more power than either her training or knowledge justified Happily that phase is passing, and the midwife now shares with the pædiatrician the nursing care of the newborn This book will be of immense value in teaching her the reasons for what she does, and moreover it never suggests that she takes any therapeutic action beyond her ability Of equal importance is the stress laid on observing those minutiæ of behaviour whose early recognition may make all the difference between death and survival

The text is liberally illustrated but, with few exceptions, the colour photographs are noticeably less effective than those in black and white

Mistakes are remarkably rare, but one on p 168 on the use of full cream dried milk, may lead to some carbohydrate diarrhœa The section on mothercraft is a little less impressive than the rest of the book, it is often open to doubt whether doctors or midwives really know more about this subject than mothers themselves

A successful future is assured for Professor Craig's book

Cardiac Diagnosis

A Physiologic Approach Robert F Rushmer, M.D, associate professor of physiology and biophysics, University of Washington Medical School Philadelphia and London W B Saunders 1955 Pp 429 80s 6d

AT the start of his clinical work, the student is often told to study the principles of medicine in his textbook of physiology Unfortunately most books on applied physiology fail to make close contact with everyday medicine, and there is a big gap between the pure physiology book and most textbooks of medicine This gap is now filled in cardiology by Dr Rushmer's valuable book It will attract all those interested in understanding the principles of cardiology, from student to cardiologist

The book is well written and illustrated, each legend being self-explanatory The selection and arrangement of the material is excellent, and everything is based on general principles which would be difficult to find elsewhere in book form As Dr Rushmer points out at the beginning of the chapter on electrocardiographic interpretation, the approach to this subject may be empirical or theoretical Successful empirical interpretation involves long experience and lengthy description, making it impracticable for most cardiologists On the other hand, the theory of electrocardiography is now sufficiently accurate to give a good working knowledge of the subject, and its principles are clearly described in this book

The logical approach sometimes results in anomalies, such as the appearance of thyroid disorders under the heading of myocardial ischæmia When hypotheses are many and conflicting the author has lost a little of his enthusiastic simplification, and this is evident in the chapter on heart-failure This is not the book in which to look for clinical details, but it is a pity to find no mention of the waterhammer pulse in the section on patent ductus The systolic murmur of mitral incompetence is described as mid systolic, finishing before the second sound, which fits neither the facts nor the theory since the pressure difference between auricle and ventricle and hence regurgitation and murmur, must be great at the time of closure of the aortic valve

Multiple Neurofibromatosis

A Clinical, Pathological and Genetical Study Frank W Crowe, M D William J Schull, PH.D and James V Neel, M D, PH D Institute of Human Biology, University of Michigan Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1956 Pp 181 36s

THIS is in essence a statistical and genetical study of 223 cases of neurofibromatosis (the word multiple is surely redundant) in Michigan

Just under 28% of these people were attending hospital for conditions unrelated to the disease, while about 18% came for cosmetic reasons only 78% had six or more cafe au lait spots, whereas no normal person was seen with this number A consistent finding of much diagnostic value was the violaceous colour associated with the tiniest neurofibromas, which from the first were papular (demonstrable by oblique light) and tended to be invaginated Another was the frequency with which osseous lesions were noted

About half the patients had affected relatives and it was calculated that the rate with which the gene or genes responsible for the trait arose through mutation must be approximately 1×10^{-4} per gamete per generation this, it is claimed, is the highest yet encountered for a dominantly inherited trait No significant intrafamily similarities in tumour location were noted except for the tendency of palmar and plantar neurofibromas to be present in some families and not in others The cases, however, were hardly numerous enough for investigation of the inheritance of acoustic neuromas

The authors make interesting observations on the pathology of neurofibromas and especially the presence in them of mast cells They draw attention to the inadequacy of most case histories of optic-nerve gliomas and hint that this condition may, more often than we think, exist in association with neurofibromatosis Further study may show that the subnormal mentality so common in families of patients with neurofibromatosis often has a structural basis

Advances in Virus Research

Vol III Editors Kenneth M Smith, F.R S, virus research unit, Molteno Institute, Cambridge, Max A Lauffer, department of biophysics, University of Pittsburgh, Pennsylvania New York Academic Press London Academic Books 1955 Pp 338 £3 4s

THE reviews in *Advances in Virus Research*, which now occupies a very useful place in the reading of those who study viruses, are written by people with first-hand knowledge of their subject so that many of the articles reach a higher standard of critical analysis than is found in most reviews The editors also do well in avoiding catalogues of references except polymyxin B, for which the control organism was a laboratory strain of *Esch coli* Sensitivity to bacitracin, neomycin, tetracycline, and chlortetracycline was determined by the disc method only, and sensitivity to polymyxin B by the quantitative method only

To measure the inhibiting effect of strict anaerobiosis on the activity of streptomycin, the sensitivity of the Oxford staphylococcus was determined under aerobic and anaerobic conditions simultaneously The effect of added carbon dioxide on the streptomycin (by lowering the pH) was examined by determining simultaneously the sensitivity of four cultures of Bacteroides in pure hydrogen and in hydrogen+5% carbon dioxide For this comparison strains were selected which grew as well in hydrogen as in the mixture of hydrogen and carbon dioxide

Sensitivity to sulphadiazine was determined by the method of Harper and Cawston (1945), usually with 10 mg of sulphadiazine per 100 ml During the earlier part of the work tests were done with 50 mg of sulphadiazine per 100 ml, but several strains gave identical results when retested with 10 mg of sulphadiazine per 100 ml

TABLE I—FREQUENCY OF ISOLATION OF VARIOUS BACTERIA FROM ABDOMINAL SUPPURATIVE LESIONS

—	Acute appendicitis (special series)	Peritonitis and abscess caused by appendicitis	Other intra-peritoneal sepsis	Abdominal wound discharges*	Total
No of specimens	13	34	18	46	111
Coliform bacilli	12	25	8	21	66
Other aerobic gram negative bacilli	0	3	3	9	15
Aerobic streptococci	7	12	4	17	40
Staph aureus	0	0	2	8	10
Micrococci and *Staph albus*	1	4	2	3	10
Other aerobes	1	0	0	4	5
Bacteroides	11	16	9	31	67
Anaerobic streptococci	10	10	5	18	43
Clostridia	2	1	2	2	7

*Selected for anaerobic incubation (see text)

Results

The organisms most commonly identified in the 111 specimens examined were Bacteroides in 67 specimens, coliforms in 66, anaerobic streptococci in 43, and aerobic streptococci in 40 (table I) The cultures of exudates on the surfaces of inflamed appendices yielded relatively more anaerobic streptococci and Bacteroides than did the cultures of peritoneal pus This difference probably reflects the greater care with which cultures from the appendices were studied The cultures were nearly always mixed, but in many specimens Bacteroides were the predominating organisms and often they were numerous Pure growths of a coliform were obtained from 3 specimens of *Staphylococcus aureus* from 3, of *Staph albus* from 1, and of Bacteroides from 1 specimen only Clostridia were usually scanty compared with the other organisms present, they were noted in moderate or large numbers in only 7 specimens, but probably were sometimes overlooked when greatly outnumbered by other bacteria

The Bacteroides strains usually grew quite easily and after forty eight hours' incubation gave colonies 0 5–1 0 mm in diameter or sometimes larger The colonies were smooth easily emulsifiable, usually greyish and semi-translucent, and with a low convex surface and an entire edge and produced no obvious hæmolysis Many closely resembled the colonies of the anaerobic streptococci which often accompanied them The growth of many Bacteroides was encouraged by carbon dioxide in the anaerobic atmosphere Eight strains were cultured simultaneously on blood agar in hydrogen and in hydrogen+5% carbon dioxide All grew well in the mixture, whereas in the hydrogen 3 grew feebly, 3 grew moderately well, and 2 gave colonies as large as those grown in hydrogen+carbon dioxide

TABLE II—SENSITIVITY OF BACTEROIDES TO ANTIBIOTICS AND SULPHADIAZINE TESTED BY THE DISC AND HARPER CAWSTON METHODS RESPECTIVELY

Antibiotic	No of strains tested	Sensitive	Moderately sensitive or doubtful	Resistant
Penicillin	57	2	3	52
Streptomycin	57	1	2	54
Chloramphenicol	57	54	3	0
Oxytetracycline	57	54	3	0
Chlortetracycline	23	22	1	0
Tetracycline	17	16	1	0
Erythromycin	54	30	17	7
Bacitracin	17	0	2	15
Neomycin*	11	0	0	11
Sulphadiazine	38	32	0	6

*Each neomycin disc contained 30 µg

Bacteroides probably were present even more often than appears from our results On several occasions we failed to isolate them although we suspected their presence from microscopy of the pus This may have happened when they were present in relatively small numbers and were therefore easily overgrown in mixed cultures, or when we were dealing with the more delicate and slowly growing varieties, or with strains which may have been destroyed by overlong exposure to the air during examination of the plates (Hine and Berry 1937) Even small numbers of *Esch coli* are readily detected in culture, but Bacteroides—even those of comparatively easy growth—must be fairly numerous if they are to be detected in the complicated mixed cultures usually obtained from abdominal pus

The results of the sensitivity tests are given in tables II and III The two methods agreed well All the strains tested were sensitive to the tetracyclines and chloramphenicol Most of them were sensitive to sulphadiazine, and more than half were fully or moderately sensitive to erythromycin Most were resistant to penicillin and to streptomycin Their resistance to *strepto*

TABLE III—QUANTITATIVE SENSITIVITY TESTS LOWEST INHIBITING CONCENTRATION OF ANTIBIOTICS FOR BACTEROIDES AND CONTROL ORGANISMS GROWING ON ANAEROBIC BLOOD AGAR

Antibiotic	Bacteroides	Control organism
Penicillin	1 strain 0 075 unit per ml 1 „ 0 15 „ 1 „ 0 6 „ 1 „ 5 0 units „ 7 strains 10 0 „ 2 „ 20 0 „	Oxford staphylococcus 0 03 unit per ml
Streptomycin	2 strains 31 2 µg per ml 1 strain 62 5 3 strains 125 10 „ 250 „ 5 „ 500 and over	Oxford staphylococcus 31 2 µg per ml (Oxford staphylococcus aerobic 1 9 µg per ml)
Chloramphenicol	1 strain 1 5 µg per ml 9 strains 3 1 „	Oxford staphylococcus 3 1 µg per ml
Oxytetracycline	2 strains 0 15 µg per ml 13 „ 0 3 „ 1 strain 1 2 „	Oxford staphylococcus 0 15 µg per ml
Erythromycin	2 strains 0 06 µg per ml 1 strain 0 12 „ 2 strains 0 25 „ 3 „ 0 5 „ 1 strain 1 0 „ 1 „ 1 0 „	Oxford staphylococcus 0 06 µg per ml
Polymyxin B	3 strains 250 units per ml 20 „ 500 „ and over	*Esch coli* 1 unit per ml

Three articles in the new volume reflect the present interest in virus nucleic acids There is a fascinating and shrewd survey by Seymour S Cohen of comparative biochemistry and virology a thorough account of the chemotherapy of viruses, with the accent on compounds which interfere with nucleic acid metabolism, by R E F Matthews and J D Smith, and a very interesting description of bacterial transformations by Harriet Ephrussi Taylor An article by J W Beard, D G Sharp, and E A Eckert on tumour viruses is concerned mainly with the Shope papilloma and avian erythromyeloblastic leucosis viruses *This is the only article* which deals specifically with animal viruses, and the views it gives will command respect if not universal agreement K M Smith discusses the development of insect viruses as *studied by morphological methods* *K Maramorosch describes* the evidence which establishes conclusively the multiplication of plant viruses in their insect vectors, a finding which is full of striking implications concerned with the origin and nature of viruses Finally, L O Kunkel writes on the phenomenon of cross protection between strains of Yellows type viruses

Das Phasenkontrastverfahren in der Hämatologie

H G HANSEN, DR MED, oberarzt, University Children's Clinic, Kiel, and ALEXANDER ROMINGER Hamburg Stormarn Verlag 1955 Pp 169 DM 16

THIS book shows very well the results obtainable with phase-contrast microscopy applied to blood and bone-marrow studies There are some 250 excellently reproduced photomicrographs, and the range of illustrations is remarkably complete Technical detail about the photographs is given, and it must be pleasant to work with such well-suited apparatus If anyone wishes to study the possibilities, and the limitations, of this technique, he cannot do better than consult this volume

---

Practical Hæmatology (2nd ed London J & A Churchill 1956 Pp 229 20s)—The second edition of Dr J V Dacie's valuable handbook is half as long again as the first Previous *sections have been expanded and new ones* added, such as those on the L E cell and abnormal hæmoglobins The book still concentrates on the quantitative tests of hæmatology and omits any descriptive morphology, for which other books are available to the student The new edition has been rewritten to such an extent that it is almost a new book The section on blood coagulation is entirely revised and now gives details of tests such as the thromboplastin generation test and the assay of antihæmophilic globulin Tests for platelet antibodies are given, but Dr Dacie finds none of them entirely satisfactory This assessment of the value of new methods is a feature we are glad to see, and it is clear that no method has been included just because it is new There is an adequate section on blood groups The detail about recommended methods is notably complete and ensures that this edition will be as welcome and as constantly used as its predecessor

Some of the Answers (Ilfracombe Stockwell 1956 Pp 160 10*s* 6*d*)—In his 25 short chapters of advice Dr G C Milner ranges over subjects great and small—from piles, colds and chilblains to religion and economics On all he has definite views Much of his advice is such as might be expected from a thoughtful and experienced family doctor and he has helpful things to say about worry and anxiety, matrimony, pregnancy, childbirth, and the elements of economics On some other subjects he is less happy Tinct quin ammon, saline douching and frequent nose blowing for the early cold, lying prone for epistaxis and scrubbing with boiled nail brush and covering with plain elastic adhesive bandage for grazes will seem doubtful expedients to many, and it is hard to believe that ' there are many occasions when a baby of six months is the better for being slapped hard across the buttocks

Histamine (London J & A Churchill 1956 Pp 472 50s)—Last year the Physiological Society and the British Pharmacological Society joined forces with the Ciba Foundation to hold a series of meetings on this subject in honour of Sir Henry Dale O M The proceedings of these symposia have now been published under the editorship of Dr G E W Wolstenholme and Miss Cecilia O Connor

New Inventions

AN ELECTRONIC STETHOSCOPE

WE have designed a stethoscope including a miniature battery-operated amplifier, contact microphone, and conventional ear-pieces Experience of existing electronic stethoscopes showed a number of undesirable features they impart a "mechanical" quality to the sounds heard in the ear-pieces and harshness in the upper register, there is a background hum, and extraneous noises are simultaneously picked up and amplified, and the stethoscopes are very costly and often cumbersome These faults have been successfully eliminated *in our* stethoscope

The microphone was designed to convey sounds arising from the source with which it is in contact and is *insensitive to all outside noises* The only extraneous *noises heard are those which resonate in the chest* or in that part of the body on which the microphone is placed

The amplifier, being compact ($1^3/_4$ in × $3^1/_4$ in × $1^3/_8$ in) *and light (18 oz)*, is easily carried suspended from the neck, and the instrument can be used wherever a stethoscope is used There are two outlets so that two people can use ear-pieces and hear identical sounds One *of the outlets can also be used for a tape-recorder* or a loudspeaker, which is excellent for teaching There are two input sockets so that two microphones may be used simultaneously

It has been found possible to attach it to a portable electrocardiograph and so obtain tracings of heart sounds, which is a most inexpensive method of phonocardiography The instrument has only three controls, of which one regulates volume and the other two restrict the upper and lower frequency ranges The latter make it possible to hear the heart sounds (which are of very low frequency) to the exclusion of breath sounds and other noises in the higher frequency range Thus outside noises in the ward or those of a passing train are completely excluded

The clinical applications of this instrument are endless, and it is ideal for teaching It enables foetal heart sounds to be picked up with ease, and murmurs related to arteriosclerotic narrowing of the great vessels are readily amplified

The apparatus is being produced by Ursonic Ltd, 11, Old Queen Street, London, S W 1

mycin was usually much greater than that of the Oxford staphylococcus, although streptomycin was less effective against this organism under anaerobic than under aerobic conditions (table III) The use of pure hydrogen in the anaerobic jar made no appreciable difference to the streptomycin sensitivity of the strains whose growth was not affected by the omission of carbon dioxide

All the strains tested with bacitracin, neomycin, and polymyxin B were resistant to these substances

Penicillin and streptomycin are often given simultaneously in the treatment of peritonitis We tried to determine whether these drugs could enhance one another's action to a degree which would make them clinically effective in Bacteroides infections Ten strains of Bacteroides were plated on blood-agar containing various concentrations of penicillin and streptomycin The presence of a subinhibitory concentration of either drug did not increase the sensitivity to the other more than twofold

During the investigation organisms apparently similar to the intra-abdominal Bacteroides strains were isolated from other sites on 41 occasions Twenty-three strains were isolated from postpartum high vaginal swabs Other sources included 1 salpingitis, 1 empyema, 1 Bartholin abscess, and 1 abscess of scrotum Most of the vaginal strains appeared to be behaving as commensals

It is not easy to determine the clinical effect of an antibiotic on Bacteroides strains in patients with intra-abdominal sepsis, because other organisms are usually present and successive samples of pus are often difficult to obtain The following case did provide evidence of the effectiveness of oxytetracycline

A man, aged 56 was operated on for pelvic appendicitis in August, 1955 An abscess was found lying against the lateral pelvic wall The remains of a partially destroyed appendix were removed with considerable difficulty In view of the extensive induration and of the possibility of an escaped stercolith having been left behind, it was felt that a residual abscess might form The patient was readmitted to hospital in October with a purulent discharge from the wound and complaining of severe low back pain, thought to be probably due to a residual abscess He was treated with penicillin and streptomycin and left hospital after five weeks He was readmitted on Nov 21, 1955, with severe low back pain and a temperature of 101°F A large abscess pointing in the right loin just above the iliac crest was opened next day and found to be tracking up from the pelvis A drainage tube was inserted, through which there was a copious discharge of pus each day until antibiotic treatment was started On Nov 24 and 26 the pus was examined , smears showed many slender gram negative bacilli and a very few streptococci, and cultures yielded a few aerobic micrococci and profuse growths of Bacteroides resistant to penicillin and streptomycin and sensitive to oxytetracycline chloramphenicol, and erythromycin The patient was given oxytetracycline 2 g by mouth on Nov 26 followed by 1 g daily On Nov 28 the discharge had diminished , a smear showed very few gram negative bacilli, and culture yielded a scanty growth of Bacteroides The same result was obtained each day until Dec 3, when oxytetracycline 3 g was given, followed by 2 g daily There after the Bacteroides disappeared from the smears, and daily cultures were sterile The amount of discharge decreased each day and ceased on Dec 7, when the patient left hospital He continued to take oxytetracycline until Dec 11, and has kept well since

Discussion

Mixed infections are the rule in intra-abdominal sepsis, and it is difficult to assess the virulence of the different organisms This difficulty applies as much to *Esch coli* (which is commonly regarded as a pathogen) as to other organisms In the absence of better criteria of virulence it must be assumed that varieties of bacteria which are commonly numerous are of pathogenic importance On this basis the most important bacteria are *Esch coli*, aerobic and anaerobic streptococci, and Bacteroides The Bacteroides are probably the most numerous of all

The treatment of intra-abdominal sepsis is, of course primarily surgical and antibiotics are by no means always required When they are, they usually must be given promptly, and the initial choice of drug must often be based on a knowledge of the bacteria usually present in similar infections

It would be wrong to dogmatise about the antibiotic treatment of a condition whose bacterial causation is as complex and variable as peritonitis Penicillin and streptomycin are often given simultaneously to control infection by gram-positive organisms and by coliform bacilli, and many surgeons believe that they are beneficial Several workers have found the tetracyclines to be effective adjuncts to the surgical treatment of peritonitis and some (Wright et al 1949, 1951, Wright and Prigot 1951 Prigot and Maynard 1955) consider that they are better than the older drugs Cantrell and Stafford (1955) found that subphrenic and other intra-abdominal abscesses followed appendicitis less often since the introduction of broad-spectrum antibiotics Our sensitivity tests showed the tetracyclines to be highly active against Bacteroides , they are also active against most coliform bacilli strepto cocci, and clostridia The tetracyclines are therefore probably superior to penicillin and streptomycin, which are unlikely to influence abdominal infections in which Bacteroides are the main agents This conclusion is strengthened by the published reports of Bacteroides infections of various organs cured with tetracyclines (Rantz 1951, Marson and Meynell 1953) Garrod (1955) also suggests that a tetracycline should be used for infections originating in the lower bowel The tetracyclines, like other antibiotics, cannot be used without some risks therefore they should not be used in conditions in which antibiotics are not clearly needed—e g uncomplicated appendicitis

Those who prefer to use penicillin and streptomycin in peritonitis should be prepared to substitute a tetracycline if these drugs prove ineffective In particularly severe infections it may be advisable to give streptomycin with the tetracycline, to ensure a more rapid bactericidal action on coliform bacilli Stern and Elek (1955) found that a mixture of streptomycin and a tetracycline had a bactericidal action on coliform bacilli and suppressed resistant variants

It should be remembered that our sensitivity tests were done with strains of intestinal origin Garrod (1955) shows that other strains may be different, especially in their sensitivity to penicillin

Summary

In 111 specimens of pus from the abdomen organisms of the Bacteroides group were often present in large numbers Other organisms which were often numerous were *Esch coli*, aerobic streptococci and anaerobic streptococci

Most of the Bacteroides strains were resistant to penicillin, streptomycin, bacitracin, neomycin, and polymyxin B All were sensitive to tetracyclines and to chloramphenicol Most were sensitive to sulphonamide and moderately or fully sensitive to erythromycin

We wish to thank Mr R V Cooke for permission to publish the case-report, and Mr L J Waller for valuable technical assistance

THE LANCET

LONDON SATURDAY, JUNE, 30, 1956

21st-Century Man

FOR many years the public of the Western countries has been warned about next century Science, the prophets have said, will destroy man He will be annihilated by atomic bombs (the products of unregenerate science), or be herded in ant-like societies whose rulers (thanks to science) can spy on him by television, influence him by waves or steal his brain and replace it with their own—projects all curiously familiar to a medical listener More respectably, man will simply starve through overpopulation caused by our folly in extending medical care to our poor relations, or become half-witted through failure to propagate an intellectual aristocracy While there is time, let him turn back, let him abandon science and revert to common sense, the tribal deities, and the past

Our generation, certainly, is qualified to recognise danger It has seen what can be done by a HITLER, and it still lives in the knowledge that a handful of psychopaths could bring human history to an end But in recognising danger we need not lose our sense of proportion, and we should know by this time that the forces most likely to translate such threats into reality are first, paranoid fear, and secondly a conviction that the future holds nothing for us Warnings we may need, but the prediction of doom through science should be seen as mostly nonsense, and its goblins as part of a psychoneurotic if not psychotic, fauna The dangers to humanity are, as always, grave, but at no time has man been better placed to deal with them The true defence is not to turn back to anything but to turn forward—not less knowledge and freedom but more This is a task which medicine and science cannot afford to neglect The faster the change in our societies, the greater the need to foresee and prepare

In a ' speculative projection of 21st-century man lately published by the California Institute of Technology,[1] it is impressive to find the writers unanimous in repudiating the starvationist ' theory of future history The world s population is increasing and will continue to do so but if the newcomers are not fed the reason will not lie in the inability of technology to feed them According to the California workers irrigation and reclaiming of marginal land, and the control of insect pests would in themselves suffice to raise food output by nearly half Beyond that lie the possibilities of new crops the substitution of synthetics and of microörganisms for animal foods, and the harvesting f the sea, where nine-tenths of the world's photonthesis takes place ' what we need said one rticipant ' is to breed a sea-going pig Work on ch lines is already in progress (some will have seen " mechanical cow built by N W PIRIE and his workers at Rothamsted), and though the appeal food research to governments is less than that of tructive undertakings, it goes on, and may go er For the California scientists the limiting factor his expansion is the availability of skilled men in the initial stages of technological revolution the number of man-hours per calorie or per kilowatt hour may fall, but it is now climbing back to, and even beyond its old level with the difference that the new kind of labour requires aptitudes and training of a very high order in a very large number of people Here the problems are medical as well as technical for psychological stress among scientists research men and skilled technicians is already clinically evident, and there would be further strains in a society which had no place for the stupid But shortage of skilled cadres—important though it may be—is not the limiting factor that we should ourselves put first If the world is not fed when technology could feed it, or healed when medicine could heal it, the reasons are most likely we should say, to lie in the form of human societies and the prejudices and interests they harbour In other words they are political

It is easy at this point to turn away, remarking that " science has no place in politics But the fact remains that the two major political issues of the world today are both of them largely issues of science—the first being the extension of high living standards to all nations, while the second is the tendency for social organisation to become a vehicle for national and personal aggression If these issues are to be dealt with by scientific causal analysis—instead of by the combination of dogma and vested interest which has hitherto been customary—the medical scientist cannot opt out of them Whether the approach of social psychology is less vitiated by personal and cultural prejudice and bias than that of ' politics as we understand it only time can show admittedly the discipline of science does not always succeed in controlling the scientist's judgments against the pull of his prejudices But it is clear that ways and means better than those of the present can and must be found

One part of the political future of man is already being influenced by science in a sense opposite to that prophesied by the pessimists In the past, societies which drew their dynamic from rigid ideologies and conformities were not seriously hampered by them in imposing themselves on the world and their neighbours In some respects these ' armoured cultures ' were at an advantage they lost their art, their literature and their capacity for enjoyment but not their competitive efficiency But once scientific technology comes to be the chief qualification which enables a society to compete this situation is likely to change In such a world ideologies have immediate and evident consequences relativity may be a philosophical concept, but if it is an erroneous one we must alter the design of our electronic equipment Thus a society may have to choose between ' bourgeois ' genetics and no beef, or between ' communistic economics and no production Moreover, the continued competitive efficiency of a neotechnic culture will depend on the attitudes of the men it produces—their receptivity, spontaneity, capacity for social action, and lack of biases—and these will be continuously exposed to practical tests When the most biased dictator of the future sets his most fanatical henchmen to build up a supersonic air force they will still be unable to train pilots without at the same time training and employing psychologists whose studies of human behaviour will call the dictator s mental state in

A NEW POSTOPERATIVE DENTAL DRESSING

DEQUADIN CHLORIDE IN GELATIN SPONGE

PHILIP TROTTER
B D S Birm., H D D Edin., L D S R C S
SENIOR LECTURER,
KING'S COLLEGE HOSPITAL DENTAL SCHOOL, LONDON

To obtain and encourage uneventful healing following oral surgery, including dental extractions, is the aim of every practitioner. Owing to the remarkable power of recovery of the oral tissues, unpleasant sequelæ are rare, and of these, septic sockets and hæmorrhage are the chief offenders. They are sufficiently inconvenient, nevertheless, to call for preventive measures to reduce or eliminate their occurrence, and for special treatment should they arise. Septic sockets embarrass both the patient and the operator. The pain and debilitation suffered by the patient with a dry socket is profound indeed, and nobody can appreciate this unless they have had one themselves.

Hæmorrhage after a dental operation may be (*a*) immediate or primary (at the time of the operation), (*b*) secondary (usually within twenty-four hours), or (*c*) recurrent (several days after the operation). There are various ways of treating these hæmorrhages, and one successful method has been in the insertion of gelatin-sponge preparations incorporating an antibiotic and thrombin. Suturing the wound and other methods may be combined with this treatment.

Thoma (1945) believes that three factors are necessary for straightforward postoperative healing:

(1) A bactericidal and bacteriostatic agent is needed because absolute asepsis is difficult to achieve and maintain during the operation.

(2) A local hæmostatic agent is desirable, because secondary hæmorrhage, although generally slight, is common during the first twenty-four hours and sometimes occurs after the hæmostatic effect of the local anæsthesia has subsided.

(3) To prevent the breakdown of too large a blood clot, thus furnishing an excellent medium for bacterial growth, a way to eliminate space must be found.

Sutton (1948) states that an agent, or combination of agents, used for this purpose should have the following properties:

(1) *Absorption*.—For immediate closure of a wound, it is essential that anything placed in it is completely absorbed.

(2) *Hæmostasis*.—To prevent oozing or slight bleeding, the material itself must be hæmostatic or allow incorporation of a suitable hæmostatic agent.

(3) *Bacteriostasis*.—The material should either have bacteriostatic properties itself or be a suitable vehicle for a variety of antibiotics.

(4) *Non-antigenicity*.—The material must not induce sensitivity or carry the risk of an anaphylactic reaction.

(5) *Clot support*.—The material must help to maintain the structure of the blood clot and at the same time it must not interfere with normal repair.

(6) *Non-irritability*.—It must not cause mechanical or chemical irritation.

(7) *Sterilisability*.—The material when used must be sterile and ease of sterilisation is important.

(8) *Ease of use*.—It must be simple to handle and insert.

(9) *Availability*.—The supply must be assured at a reasonable cost.

Materials Previously Tried

Several such materials have been developed and investigated in recent years, including alginates, oxidised cellulose, fibrin foam, and gelatin sponge. Gelatin sponge seems to conform most closely to the ideal substance. In the past, gelatin sponge has been used almost entirely in the prevention and control of postoperative hæmorrhage and for eliminating the "dead space" in large closed oral wounds. It has also been used for socket implantation after extractions. In the closed wounds, the gelatin sponge seemed effective and was absorbed without putrefaction. In open wounds it often became foul and healing was impaired—probably because it acted as a culture medium. Unpleasant sequelæ have also been reported by Jenkins (1946), Taylor and Kaplan (1950), and Moore et al. (1954).

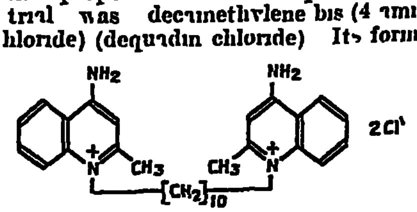
Sponge soaked in penicillin reduced the sequelæ to some extent, but views differ about how much penicillin to use (Fleming and Fish 1947, Silverman 1949) and there is always the danger of sensitisation and the production of resistant organisms. Other disadvantages were that some bacteria were already penicillin resistant, penicillin is inactivated by serum, and the technique is time consuming. Whether the penicillin remains active in the tooth socket for long enough to achieve any worthwhile bacteriostasis is also debatable; the findings of Holland and Tain (1954) suggest that it does not.

It seemed that a more effective bacteriostatic or bactericidal agent must be found and incorporated; for Silverman (1949), using the sponge alone, noted that there was no variation in incidence of postoperative pain, compared with untreated sockets. Results in the extraction clinic (local anæsthesia) at King's College Hospital agree with this finding.

A New Combination

After unsatisfactory trials, using various materials, had been carried out in the dental department of this hospital, a new combination was evolved. This consisted of gelatin sponge impregnated with 0·1% 'Dequadin chloride'.

During the development of laudexium ('Laudolissin'), *a synthetic muscle relaxant of the true curarising type*, it was observed that solutions of the drug had considerable antibacterial activity. Many simpler related compounds were therefore synthesised and tested for antibacterial properties. The compound selected for clinical trial was decamethylene bis (4-aminoquinaldinium chloride) (dequadin chloride). Its formula is:



Its antibacterial properties and pharmacology have been investigated by Babbs et al. (1956). Its salts inhibited the growth of all microbial species used in

question, and engineers who, if their machines are to leave the ground, will be unable to accept the dogma that 2=3 However much we allow, as we must, for the human power of double-think, which affects scientists as much as (some would say more than) their fellows, the continued growth of analytical and purposive study of Nature must give rise to more analytical and purposive study of ourselves, of society, and of the pretensions of would-be leaders or rulers

21st-century man will have his own troubles He may look back at ours as an age of inequality and ideology, in which societies still delegated authority to essentially aggressive or prohibitive people, as the age in which it became possible first to control disease and hunger and then (by applying the same methods of thought) to control the antisocial, irrational, and incoordinate sides of human conduct which obstructed the application of knowledge, and possibly as the golden age of science in general Since the exponential progress of knowledge can hardly go on indefinitely without some pause, our grandsons may spend the 21st century in drawing breath, and in allowing civilisation to catch up with the practical and intellectual progress made in the time of strife and excitement which preceded it But if they read our literature, they will have less respect for the Jeremiahs and the Jonahs who foretold judgment than for the Ezras who urged their contemporaries to rebuild the Temple

British B.C G

THE rather tentative official support for B C G in this country in the past few years has been fortified by a statistically unassailable experiment[1], and, although the vaccine cannot yet be freely used, there are signs that control is being relaxed So far all the B C G vaccine routinely used in this country has been imported But the first report of a British B C G, a freeze dried vaccine, has now appeared[2] Freeze dried vaccine, if it is as consistently potent as the liquid products, has obvious advantages It can be kept for many months at room-temperature without serious loss of potency, so that each batch can be fully tested before it is released Instead of having to be ordered in advance and used without a delay, the freeze dried product can be kept in store and is promptly available—an obvious advantage to those who use it infrequently and in small quantities Freeze-dried vaccines have been manufactured and tested in many countries, notably in France,[3] the United States,[4] Russia,[5] and Japan[6 7] The extensive Japanese experience of its manufacture has recently been reviewed by OBAYASHI in a W H O monograph[8]

The new British vaccine was produced in the Glaxo laboratories and after detailed bacteriological and animal tests, two batches were put to clinical trial LORBER and his colleagues[2] vaccinated 276 newborn infants After six weeks 88% of those vaccinated with one batch and 77% of those vaccinated with the other gave a positive tuberculin skin reaction But twelve weeks after vaccination the proportions of "converters" had risen to 96% and 92% This delay in the appearance of the sensitivity produced by freeze-dried vaccine was also noted by EBINA et al The vaccination lesions were small and in only 8 infants were there palpably enlarged axillary lymph nodes None had any detectable general disturbance of health The vaccine was kept at room-temperature during the fourteen weeks of the trial There was no important change in the vaccine during this period and counts of viable cells were of the same order as at the start of the investigation LORBER et al believe that this particular British freeze dried vaccine would not be suitable for vaccination of contacts, for it may be desirable in contacts to induce tuberculin skin sensitivity as quickly as possible with the least risk of failure This is, however, not a serious deficiency, for most of the vaccine required in this country will probably be needed for routine vaccination of those not especially exposed to infection

Hypercalcæmia in Infancy

SINCE the benign[1] and severe[2] types of idiopathic hypercalcæmia in infancy were first described, many cases have been recorded,[3–16] and we have from time to time discussed these developments[17 18] The clinical pattern is well defined anorexia, vomiting, constipation, and failure to thrive, with raised serum calcium and blood-urea levels The outlook in the simple group is generally good, although there have been occasional deaths, but in the severe type, with physical and mental retardation, patchy osteosclerosis, renal failure, and hypertension, recovery is often incomplete and death is not rare In a recent issue Dr MORGAN and his colleagues[19] described 15 cases seen in Dundee during a period of two years and they gave a detailed account of metabolic studies in 2 hypercalcæmic infants Their conclusions confirm previous reports of high calcium retention,[8 11 15 20] and the beneficial effects of low-calcium diet and of cortisone,[9 21] which, they found, increased the fæcal calcium Dr MORGAN and his associates do not favour the use of calcium-chelating agents, such as disodium ethylenediamine-tetracetic acid (E D T A) because of the gastro-intestinal irritation they produce Like most of those who have studied this syndrome, they feel that the most likely cause is an over action of vitamin D Dr LIGHTWOOD and his colleagues in the pædiatric unit at St Mary's Hospital, London, laboratory investigations, including gram-positive, gram-negative, and acid-fast bacteria, and fungi including *Candida albicans* Unlike many other quaternary ammonium salts it was not inactivated by serum

Gelatin sponge impregnated with dequadin chloride was used in two ways. (*a*) when the dental surgeon judged that postoperative sequelæ were likely it was used prophylactically and (*b*) when postoperative complications were present, it was used as treatment

It was used prophylactically in over 900 cases in which extractions were performed under local anæsthesia In many of these more than one tooth socket was so treated Pieces of gelatin sponge were inserted into the wound immediately after extraction, before a covering pack was placed over the wound (a normal routine procedure) The sponge was lightly inserted care being taken not to consolidate it before putting it in or to pack it tightly into the socket If the sponge was consolidated. the results were less satisfactory The wound was sutured when necessary in these cases it was easier to place the sponge in the wound after inserting the sutures but before tying them because the sponge tended to be squeezed out of the wound during suturing

In approximately 97% of the cases healing proceeded normally. and in many of these hæmorrhage or dry sockets would, judging from the history and the conditions at operation, have almost certainly ensued without the prophylactic use of the dequadin chloride sponge There was no postoperative hæmorrhage in any of the prophylactically treated cases Although a few septic sockets developed despite prophylactic treatment, most of these involved either lower impacted or buried third molars or sockets where excessive extraction manipulation had previously occurred

When a dry socket resulted it was treated with the dequadin sponge, upon which was deposited a few drops of a sedative such as 'Dentalone' The patient was told to report back if pain and lack of healing persisted In almost all of the cases treated a further visit was unnecessary If they did return the dequadin sponge plus dentalone dressing was repeated when there was pain present, the dequadin sponge alone was used if the pain had subsided

Many varied treatments for dry sockets have been tried in this department, but this technique has been the most satisfactory so far

Patients who had had difficulties after previous dental extractions reported good healing with the prophylactic therapy

Hæmorrhage from sockets not treated prophylactically was treated with dequadin impregnated sponge sutures were sometimes used No septic socket followed this treatment, as has happened previously when ordinary gelatin sponge or oxidised cellulose gauze had been used, and no swelling supervened though this was a common event with sockets treated with cellulose gauze

Conclusion

Dequadin chloride, a potent non-toxic, and non-irritant antiseptic appeared to supplement the gelatin-sponge therapy by preventing and counteracting infection in the wound. by preventing putrefaction of the sponge, and by encouraging healing Compared with the results of previous investigations of postoperative complications there seemed to be a reduction in the incidence of such sequelæ when the dequadin chloride sponge was used No definite conclusion can be drawn because of the unknown variables, but our observations suggest that it is a valuable treatment The incorporation of dequadin chloride into gelatin sponge may have a wider application in general surgery and medical practice

My thanks are due to Dr R Cocker director of dental studies for permitting this investigation to my assistants Mr P Belsham, Mr G Hawkes Mr L. Shinn Mr T Farrell, and Mr W Johnson, and to the medical and research departments of Messrs Allen & Hanburys for their coöperation in producing and supplying the experimental dequadin-chloride sponge

The number of published reports of cryptococcosis is relatively large Collins et al (1951) reviewed 241 cases and Cohen and Kaufmann (1952) 220 In each of the published cases *Cryptococcus neoformans* was the pathogenic agent On invading the body this yeast usually attacks the brain and meninges, causing subacute or chronic, but almost invariably fatal, disease. The lungs have been suggested as the most likely portal of entry but Hirsch and Coleman (1929) assumed that, when the meninges were affected, the yeast invaded them via the nasopharynx The central nervous system has been estimated to be involved in a third of the cases of pulmonary cryptococcosis by Langeron and Vanbreuseghem (1952) and in 42% by Swartz (1949)

Primary pulmonary cryptococcosis that remains localised to the lungs is rare Linden and Steffen (1954) knew only 9 cases including 1 of their own Since then single cases have been reported from Belgium (Van Goidsenhoven et al 1954), Canada (Eisen et al 1955) and Hungary (Vitez et al 1955) Only 4 of the cases so far published were of the disseminated nodular type

Cox and Tolhurst (1946) are of the opinion that primary pulmonary cryptococcosis is more common than one would expect on the basis of reported incidence These workers believe that cryptococcosis often escapes detection owing to spontaneous recovery and to lack of spread and of signs and symptoms Beck et al (1955) agree with this view

In the case reported here the infecting yeast was *C luteolus* which is closely related to *C neoformans*

Case-report

A girl aged 4½ years was admitted to this hospital with the diagnosis of recent measles present whooping cough, and suspected submiliary tuberculosis of the lungs She had begun to cough sixteen days earlier and had had an exanthem suggesting measles eight days before admission. Four days before admission she had pyrexia (102.2°F) and was given four injections of penicillin for supposed pneumonia Case notes which accompanied her from another hospital said that auscultation had revealed diffuse crepitations areas of bronchial breathing, and râles in the lungs The liver had been enlarged, its lower margin being palpable 4 cm below the right costal arch No other physical changes had been detected lately described[22] the management of a single case of hypercalcæmia with a virtually calcium-free milk The calcium balance was strongly positive during the active stage, it became negative on a low-calcium diet, and more strongly so when a low-calcium cereal was given in addition This change may be due to the high content of phytate and inorganic phosphorus in the low-calcium cereal the consequent binding of intestinal calcium would increase the fæcal loss Cortisone had a quicker initial action, but there may be undesirable side-effects, such as the risk of intercurrent infection A diet low in calcium is difficult to prepare and manage, but it seems to give adequate results without the hazards of cortisone A point of great interest in the St Mary's patient was the disappearance of hypertension and cardiac murmur during treatment these are signs usually found only in children severely affected It seems likely that the clear-cut distinction between the simple and severe cases[23] is to some extent artificial, since examples of an intermediate type occasionally appear

Last week Dr **Forfar** and his colleagues discussed 5 cases of infantile hypercalcæmia, and a possible 6th They are not satisfied that the syndrome can be fully explained on the basis of intolerance to vitamin D As points against the vitamin-D hypothesis, they showed that some at least of these infants were not particularly sensitive to large doses of calciferol, and that calciferol does not increase the urinary output of calcium, as would be expected in hypervitaminosis D They also showed that, in 1 child, citrate metabolism was more in keeping with rickets than with hypercalcæmia In 4 out of 5 cases they found an increase in plasma-cholesterol levels—a finding previously reported[8–10 16 20] without comment Their conclusion, with statistical support is that there is a significant positive correlation between serum-calcium and plasma-cholesterol levels, which would not have been expected had the cause of the condition been vitamin-D intoxication Idiopathic hypercalcæmia of infancy may result, they believe, from a disturbance of cholesterol metabolism leading to the formation of a toxic calcium-raising substance of sterol type allied to vitamin D, which itself may be an aggravating factor The cholesterol disturbance may be due to infection This is an attractive if rather speculative explanation The points against vitamin D will require confirmation, and future research might include an effort to link this disorder of cholesterol metabolism with the abnormality of plasma vitamin-A levels reported by **Fyfe**[24] He found in 8 cases that the fasting and post-absorption levels of vitamin A were higher than in controls Even if no direct relation were to be found between these two findings, further work might reveal other and more fundamental disturbances of fat metabolism It should not be overlooked that both cholesterol[16] and vitamin-A derangement[25] could be secondary to a renal lesion as has been found in the nephrotic syndrome One point which is hard to explain on the cholesterol hypothesis is why the condition so common in Great Britain and Northern Ireland should be virtually unknown in North America, where the diet and infections of infancy are little different from those of this country

Another contribution to this subject appears on an earlier page of this issue, where Dr **Rhaney** and Dr **Mitchell** extend the pathological picture in a report of three children who died of hypercalcæmia The most striking lesion was renal calcification, mainly medullary These changes are non-specific and have been found in hypervitaminosis D, renal acidosis, and in other diseases of infancy

From the evidence which has accumulated in recent years, we may conclude that infantile hypercalcæmia is a relatively common condition in Britain, that it is the cause of much ill health and interference with growth, and that it is sometimes responsible for mental defect and even death As Dr **Rhaney** and Dr **Mitchell** point out, the evidence implicating vitamin-D intoxication in idiopathic hypercalcæmia is, at the best, circumstantial Much obviously remains to be done to define the ultimate causes, and in the meantime we should acknowledge that the recognition and better understanding of this peculiar syndrome have led us to realise that many babies in these islands are now receiving more vitamin D than they require[26] If a general reduction in the intake of vitamin D to physiological levels (say, 400 to 800 international units per day) were to be followed by a decline in the incidence of hypercalcæmia throughout the country, the case against vitamin D would be the stronger Until the problem is solved, babies should be given doses of the vitamin within the physiological range which we know to be adequate in protecting nearly all of them against rickets

Annotations

THE ROYAL NORTHERN HOSPITAL'S CENTENARY

At the age of 30 Sherard Freeman Statham was a promising assistant surgeon at University College Hospital when, on May 14, 1856, he playfully slapped the exposed buttocks of a man on the operating table, thereby raising a laugh from the class John Erickson, the professor of surgery, who was about to operate, later reported this boisterous episode to the dean of the faculty He complained, too, that his spirited colleague had, on the same day used improper adjectives and expletives to a patient who was reluctant to inhale the chloroform before " a very dangerous capital operation " The council of University College deplored such conduct and after interviewing Statham and hearing the views of the medical and lay committees, they directed that he should cease to be assistant surgeon The disconsolate surgeon returned to his rooms at 42, Mortimer Street, and what passed through his mind we do not know But he was not one to remain idle for long and his restless energies were soon directed, it seems, to the mounting needs of the poor of North London, for whom medical and surgical care barely existed He thereupon secured the lease of modest premises in York Road (now York Way), King's Cross, and, with the support of his dentist brother, and of Dr G F Whidborne and Dr C P Croft, he founded the Great Northern Hospital with some 16 beds The doors were opened one hundred years ago, on June 30, 1856

The story of this great hospital's achievements from its beginnings to the present day has been recorded by Dr E C O Jewesbury in a fine history[27] prepared

[27] The Royal Northern Hospital 1856–1956 By E C O Jewesbury M D M R C P London H K Lewis 1956 Pp 157 17s 6d

There was said to be an increased amount of urobilinogen in her urine, and a blood count had shown red cells 5,160,000 per c mm , Hb 80%, and white cells 31,000 per c mm (polymorphs 31% lymphocytes 61%) Radiography of the chest had revealed in both lungs numerous disseminated soft nodular shadows and distension of hilar shadows with bundle formation suggesting tuberculosis A Pirquet test and a Mantoux test in a dilution of 1 1000 had been negative Lumbar puncture had produced clear cerebrospinal fluid (C S F) under increased pressure and containing no cells Pandy and Waltner tests had been negative

On admission to our hospital the patient was moderately developed and thin, weighing 12 6 kg She had cyanosed lips and nails On her skin a few pigmented spots were visible like those of measles No abnormality was found on percussion of the chest, but on auscultation extensive diffuse metallic moist râles were heard over the lungs The pulse rate was 120, with the pulse rhythmic, equal, and easily suppressible The cough was typical of whooping cough No symptoms or signs suggesting involvement of the central nervous system were detectable

Investigations —A considerable amount of urobilinogen was present in the urine A blood count showed red cells 4,420,000 per c mm and white cells 20,000 per c mm (polymorphs 39%, lymphocytes 59%, plasma cells 2%) The erythrocyte sedimentation rate (E S R) was 16 mm in the first hour (Westergren) A Mantoux test in a dilution of 1 1000 was negative

Treatment and Course —The child was given 'Tiocomycin ' 4 g in four days and penicillin 8,400,000 units and streptomycin 5 6 g in fourteen days Pyrexia disappeared in four days, but later her temperature rose again slightly Coughing subsided, and she began to gain weight Sixteen days after admission she again had pyrexia (104°F), and physical examination revealed insignificant changes in the lungs The E S R was 75 mm in the first hour (Westergren) A blood count showed red cells 4,360,000 per c mm and white cells 16,800 per c mm (metamyelocytes 4%, polymorphs 68%, eosinophils 2%, monocytes 3%, lymphocytes 23%) The urine was practically normal Blood culture remained sterile Lumbar puncture produced clear C S F under normal pressure and containing 10 cells per c mm , protein 0 28 mg per 100 ml , and sugar 63 mg per 100 ml A Pandy test showed slight opalescence Nothing abnormal was found in the central nervous system Radiography of the chest (fig 1) revealed ill defined round opacities of different sizes in both lungs, decreasing in number hilifugally , they had no definite outlines and were found mainly in the upper lobes They were somewhat fewer at the apices and considerably fewer in the inferior lobes and near the diaphragm The hilar shadows were of normal density and showed no extension Both halves of the diaphragm had sharp outlines and moved freely The heart was normal in shape, with a slight bulging of the pulmonary arc The mediastinum was free Since this radiographic pattern did not fit the picture of any known disease, especially submiliary pulmonary tuberculosis, it was suggested that the changes might be due to mycosis To exclude tuberculosis Mantoux tests were made on Nov 2 and Dec 28, 1954 and on Jan 7, 1955 The results were all negative, although the dilution used was 1 in 100 Bronchial swabs obtained on laryngoscopy were sent to the mycological laboratory of the State Institute for Public Health on Oct 12, Oct 23, and Dec 22, 1954 They were taken via a rubber tube introduced into a bronchus through a laryngoscope

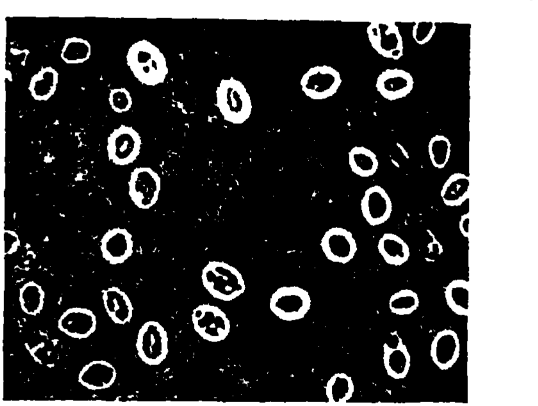

Fig 2—Microscopical appearances of a pure culture of *Cryptococcus luteolus* in china ink

Mycological Studies —Three samples of bronchial secretion taken in this way grew a yeast on media commonly used for this purpose (Sabouraud agar, malt agar, blood agar, and malt extract) and typing was according to Lodder and Kreger Van Rij (1952) All three samples were centrifuged, and the sediment was mixed with china ink and examined microscopically, yielding one ovoid or elongated, sometimes budding and encapsulated, organism to every two or three fields From each sample a pure culture of a blastomyces was recovered All three cultures were identical, and the yeast had the following main properties On growth at 26°C for three days in malt extract elongated or oval, sometimes budding cells, about 4 μ × 6 μ, were detectable Pseudomycelia and hyphæ were absent A thin film was present on the surface of the fluid medium The cells grown in malt extract at 26°C for thirty days were enclosed in a thick mucous capsule Growth in Sabouraud agar at room temperature or at 37°C for thirty days produced a highly lucent, yellowish brown, definitely mucous colony at the bottom of the test tube After thirty days' growth in Gorodkowa and Adams agar at 26°C or at 37°C asci were not detectable by spore staining In corn meal agar no chlamidospores were formed The organs assimilated glucose, galactose, maltose, and saccharose, but not lactose or potassium nitrate, and did not ferment carbohydrates These characters identify the organism as *C luteolus* (fig 2)

Animal Inoculation —10 mice were inoculated intracerebrally with a heavy suspension of the yeast in physiological saline solution The mice had no signs during sixty days' observation Then another 6 mice were inoculated in the same way and these too were free from signs when killed sixteen days later We failed to grow the yeast from the brains of these mice and attempts to detect it by direct examination failed Histological examination yielded negative results The intracerebral route of inoculation had been chosen in view of the fact that this method proved to be the most efficient for demonstrating the pathogenicity of the closely related *C neoformans* Experimental evidence was obtained that *C luteolus* did not affect the central nervous system of the mouse Since our patient had no nervous symptoms either, it has been suggested that this yeast may act specifically on the lung only To elucidate this point, experiments on animals are being made in which the yeast is introduced directly into the lungs by intrathoracic injection and by aspiration

Course of Patient's Illness—Until the final results of the mycological studies were available the patient was given an additional 19,000,000 units of penicillin, 18 g of streptomycin

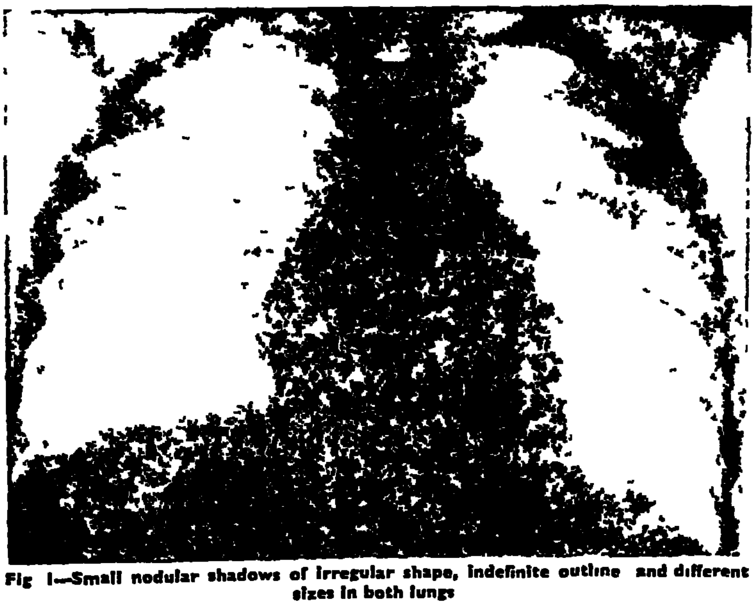

Fig 1—Small nodular shadows of irregular shape, indefinite outline and different sizes in both lungs

for the centenary. The early days were spent in the densely populated neighbourhood of the New Cattle Market and the Great Northern Railway Station with its growing maze of goods yards. Within twelve years the lively embryo of a hospital had outgrown its premises so that the next stage had to be spent in Caledonian Road. Here artisans and labourers in need of attention flocked to the well managed outpatient department, where finely dressed people were refused admission. Three quarts of cod-liver oil and an ounce of quinine were dispensed each day, and a donation of half a crown was guaranteed to secure immediate attention. As we said at the time, it was a *model outpatient department*. In 1888, however, a newly built and fully grown hospital, the pride of Islington and the adjoining districts, first graced the Holloway Road, and there it has remained. Poor Statham, whose initial contribution of £1430, so generously given, appears to have been followed of necessity by other donations, died at 32 of phthisis. He was a bachelor and left only £500. The "Founder of the Great Northern Hospital, London" is buried at Stone, near Aylesbury, in the church where he was baptised. The scarlet tunic with epaulettes, and the trousers, which he wore in the Schleswig Holstein campaigns, together with his watch and medals, are preserved as a memento of an erstwhile gallant soldier who had early interests in war surgery and army hygiene. Perhaps it was indifferent health which deterred him from going to the Crimean War as he had asked to do, and perhaps the subsequent frustration accounted for those indiscretions which led to his dismissal from University College Hospital—and to the foundation of another charity.

The Royal Northern Hospital, it may be justly said, has had a meteoric career. From the start it attracted fine consultants, zealous administrators, and boards composed of far sighted laymen. It has also been fortunate in securing, throughout most of its life, the patronage and continued interest of the Royal Family. Successfully it overcame the threat of insolvency, and in doing so it was the first to introduce such things as pay-beds which at the time (1894) were opposed on principle by the general practitioners of North London and by *The Lancet* and *British Medical Journal*. But when, in 1888, a heavy legacy duty deprived the hospital of much-wanted money, we spoke sharply in support of the Royal Northern. "In other countries the State maintains the hospitals. In ours this duty is not only thrown on private individuals, but even their charity is taxed."

Quite apart from its merits as a story Dr Jewesbury's book will give encouragement to those who believe that the tradition of voluntary service need not lapse because funds for the hospitals are now provided publicly.

THE BLIND IN OUR MIDST

In the next twenty years the blind in England are likely to increase in number from the present 94,000 or so to 140,000 or more, and by 1958–59 schools for the blind will have to cater for some 2200 children, instead of some 1400 as in recent years. These forecasts, amply supported by figures, are contained in the latest of Prof. Arnold Sorsby's valuable periodic reviews.[1] Professor Sorsby finds that registrations of blindness increased by over 7000 between March, 1952, and the end of 1954. This increase is accounted for mainly by blindness in those aged 70 or over; in 1954, 69% of those newly registered as blind were in this age group. Accordingly there has been a steady increase in the proportionate incidence of blindness due to senile macular degeneration. There has also been some increase in those aged 1–4 and 5–15. Retrolental fibroplasia is the cause of blindness in more than half of those aged less than 1 and rather more than 25% at ages 1–4. (The geographic distribution of retrolental fibroplasia is uneven. "It would almost seem as if there is a central island area in the country with a low incidence.")

As regards prevention, cataract is the one *important* cause where fuller exploitation of existing measures should help to reduce the incidence of blindness. Among the new registrations in 1951–54, 84% of those with cataract had had no treatment. At registration many of these patients are old and frail, but they could probably have undergone operation comfortably and safely some years earlier. Of clinical developments, Professor Sorsby writes:

> "If the congenital and hereditary affections are included amongst the general medical disorders, some 80 per cent or more of the blind under 50 present fairly well defined problems in general medicine. Hope in these affections lies not in an expansion of the surgical facilities available, but in the creation of clinical units which can draw on the potentialities of both ophthalmology and general medicine, even if this involves some departure from the traditions of ophthalmology as an essentially surgical speciality."

DORMEZ-VOUS ?

Is Frère Jacques restless? And does Cheselden stir a little in his grave? The era of lithotomy may be giving way to an age in which stones are dissolved by a method founded on logical chemical precepts. Since we reviewed[1] this subject Lagergren[2] has described his biophysical investigations of urinary calculi. His findings from the examination of 600 calculi by X-ray diffraction confirm those of earlier workers—namely, stones are not the simple affairs our clinical nomenclature implies. The stones he studied were composed of a complex mixture of eleven distinct crystalline substances, and in one stone a substance defying identification was observed; whewellite, weddellite, apatite, and struvite were common, but uric acid was relatively uncommon. *Microradiography showed the distribution of the various substances within a stone*: a stone might have a core of one substance surrounded by another, and in a laminated stone made up of different substances each lamella consisted of one component only—as though the chemical, and, therefore metabolic, factors contributing to its growth changed during its existence. Such studies, together with an understanding of the architecture of a stone, as revealed by microradiographs, provide the proper foundation for treatment, since exploration of the biochemical processes involved in the formation of stone cannot possibly begin until it is known what stones are.

Even with our knowledge as it stands today we use chemical methods in an attempt to prevent the recurrence of stone formation—by decreasing the crystalloids in the urine, by preventing with hyaluronidase their aggregation or increasing their solubility by acidification or alkalinisation, as the case may be, or by preventing the absorption of phosphorus from the alimentary tract. Treatment on these lines is, however, a severe imposition on the patient, who has either to maintain permanently an unpalatable diet or continue to swallow unpleasant aluminium gels. Furthermore, each remedy is specific for what is thought to be the substance of the stone, within the crude and erroneous categories of oxalate, urate, and phosphate. And what practising urologist today has sufficient technical assistance to discover the nature of the core of a patient's stone? The substance at the core is of primary aetiological importance since it may differ and 7 6 g of isoniazid The pyrexia subsided by lysis, and the patient remained apyrexial for the rest of her stay in hospital except for a slight rise of temperature for a few days She developed mild hepatitis on Oct 9, but recovered from it uneventfully Vitamins and tonics were given, and the patient was entirely free from symptoms The changes in the lungs detected by radiography remained stationary for a long time and were not influenced by administration of 'Paraben' 3 g given over three days Later the radiographic appearances slowly changed beginning in the less affected inferior lobes and spreading gradually to the upper lobes

[2] Biophysical Investigation of Urinary Calculi. By CURT LAGERGREN. Stockholm, 1956. Sw. Kr. 25. *Acta radiol., Stockh.* suppl. no. 133.

Discharge and Follow up—The child was discharged on Jan 26, 1955 when she was completely free from symptoms, had no complaints whatever, and weighed 15 7 kg She has since been examined at intervals of three to four weeks, and her E S R and blood counts are persistently normal Radiography of her chest on June 28, 1955 showed practically no nodular shadows In both hilar areas, around the upper pole, there were numerous thick bundles with a few small pale nodular shadows, with indefinite outlines, on the right side only The lower pole of the hilar areas showed a few soft trabecular shadows running towards the diaphragm

Discussion

Of the 9 cases of primary pulmonary cryptococcosis reviewed by Linden and Steffen (1954) 5 were diffuse pulmonary affections (2 the small nodular type) and 4 torulomas The present case was a toruloma Similar pulmonary changes have been described by Van Goidsenhoven et al (1954) and Eisen et al (1955) The present case resembles that published by Eisen et al also in that the radiographic changes did not fit the pattern of any of the diseases that should be considered in the differential diagnosis This fact pointed to mycosis, and the suspicion was borne out by cultural examinations in all 3 cases

In assessing the radiographic changes in our patient's lung, residual changes due to preceding measles and whooping cough had to be considered too In the published cases mentioned and in our case there were, however, certain radiographic signs which were somewhat typical though not pathognomonic hilar involvement was either absent or very slight, disseminated nodular lesions were present at the apices and near the diaphragm in very small numbers only or not at all, and the single nodular shadows varied in size and shape, and their outlines were less definite than those of tuberculous lesions This agrees well with the histological findings of Hirsch and Coleman (1929) who found, in their patient with secondary pulmonary cryptococcosis associated with meningeal involvement, nodular pulmonary lesions whose outlines were irregular and less definite than those of the lesions of miliary tuberculosis The nodular lesions in the present case were present in the upper lobes, which is also in accordance with what Hirsch and Coleman found

It is the mycological evidence, however, that gives particular significance to the present case In all the cases published so far the pathogenic agent was *C neoformans*, but in the present case the yeast recovered from all three specimens of bronchial secretion obtained by direct suction was *C luteolus*

C leuteolus was first isolated from air by Saito in 1922, in Tokyo, by the method of Lodder and Kreger-Van Rij This yeast is extremely rare, and this is the first time that it has been found in Hungary It is closely related to *C neoformans*, the well-known pathogen causing cryptococcosis The two species differ but slightly in morphology, inasmuch as on growth under identical conditions the *neoformans* cells are spherical and the *luteolus* cells ovoid or elongated In view of the close relationship between these two species, Lodder and Kreger-Van Rij (1952) direct attention to a potential pathogenicity of *luteolus* and emphasise the importance of experiments on animals

Although so far we have not been able to prove experimentally that this yeast can act as a pathogen, we can assume that it can do so in man, because in the present case no other pathogenic agent was detected by radiographic clinical, or microbiological methods

Summary

A case of diffuse pulmonary infiltration, associated with *C luteolus*, in a girl aged $4^1/_2$ years is described

C luteolus was recovered on three occasions from bronchial secretion obtained on laryngoscopy

We have been unable to find any published report that *C luteolus* is pathogenic to man Its pathogenicity to animals also still awaits final corroboration

C luteolus is closely related to the well-known pathogen *C neoformans*

CORTISONE THERAPY IN EARLY PREGNANCY RELATION TO CLEFT PALATE

JOHN W S HARRIS
M B Lond, M R C O G
DEMONSTRATOR OF ANATOMY,
LONDON HOSPITAL MEDICAL COLLEGE

IAN P ROSS
M D Lond, M R C P
MEDICAL REGISTRAR, LONDON HOSPITAL

WE report here the occurrence of a cleft palate in a baby whose mother received cortisone therapy in early pregnancy, and review the experimental evidence that cortisone treatment of laboratory animals in early pregnancy may lead to congenital cleft palate in the offspring

Case-report

A woman, aged 30, with four years' history of idiopathic steatorrhœa was treated with a gluten free diet, oral iron, and vitamins, but her condition remained unsatisfactory, and persistent diarrhœa and anæmia led to her third admission to hospital for trial cortisone therapy

On admission on Nov 9, 1954, she was pale and thin, and weighed only 6 st 8 lb Chvostek's sign positive Œdema of legs Abdominal and pelvic examination normal Hæmoglobin 71% (Haldane) (10 5 g per 100 ml) Serum calcium level 6 5 mg per 100 ml Plasma protein level 5 2 g per 100 ml (albumin 2 9 g per 100 ml, globulin 2 3 g per 100 ml) Fat balance 80% absorption over 4 days

Gynæcological and Obstetrical History—Menarche at the age of 13 Normal menstrual loss lasting 5 days Cycle predominantly 28 days, but periods of amenorrhœa lasting 2–3 months had occurred, notably after the previous admissions to hospital Last menstrual period (Oct 8–12) began 32 days before her admission First pregnancy at the age of 24, threatened abortion in first trimester but otherwise uneventful, terminating in the spontaneous delivery of a full term normal baby At the age of 26 vaginal bleeding after 10 weeks' amenorrhœa, the cause of which was unknown, but pregnancy could not be excluded

Family History—No known congenital defects on either side of family

Progress—Treatment with oral cortisone 100 mg t d s and normal diet was begun on Nov 29 In view of the menstrual history and the negative findings on examination no significance was attached to the 8 weeks' amenorrhœa The patient's general condition improved, and the dose of cortisone was reduced (see fig 1) On Jan 3 1955, she was discharged home on a maintenance dose of cortisone 12 5 from the cortex and thus provide the clue to the initial metabolic disturbance The method of attack advocated by Prien and Walker[3] has much to recommend it Apatite (basic calcium phosphate) is the commonest substance in urinary stones, moreover, half those stones which are predominantly calcium oxalate are found to have formed around a small nucleus of calcium phosphate In its detoxicating function, glucuronic acid is excreted as a glucuronide in conjunction with the substance to be eliminated, by giving salicylate the glucuronide content of the urine is increased, and glucuronides increase the solubility of calcium phosphate, in proportion to their concentration Prien and Walker have given both acetylsalicylic acid and salicylamide with good results to 19 patients subject to recurrent stone, with effective suppression of stone formation in 17, with the encrustation of indwelling catheters was also prevented thereby

Here, then, is a biochemical approach to treatment which commits the patient only to a familiar pill It is not inconceivable that solution of stones already formed may eventually be achieved along these lines So Dr Whytt[4] and Joanna Stephens may yet have the last laugh over the lithotomists Their principle was correct, though the effective solvent is unlikely to be lime water and soap or a concoction of calcined snails, the seeds of wild carrot and burdock, hips and haws, all burnt to a blackness and mixed with soap and honey[5]

A FURTHER OUTBREAK

The return (announced in the *Times* of June 21) of the infection which appeared about the same time last year, and led to the closure of the Royal Free Hospital for several months, raises questions which were left unanswered by the group of articles which we published on May 26, dealing with what seems to be the same disease The full report of last year's outbreak—which affected all grades of the Royal Free staff (residential and non-residential, medical and non medical) but left the patients virtually unscathed—is eagerly awaited for any light it may throw on ætiology and length of incubation period From the available evidence the incubation period seems to be not longer than a week, but we do not yet know whether a patient who has a relapse (as many have done) regains infectivity in the process

The resemblance to encephalitis lethargica in a mild form is too striking to be ignored after an initial period characterised by malaise, nausea or vomiting, somnolence, and slight fever, accompanied in most cases by ocular manifestations such as diplopia and nystagmus and occasionally by otitic symptoms such as tinnitus, neurological features appear in a varying proportion—some transient, others lasting months or even years Emotional lability with hysterical symptoms is a conspicuous feature of severe cases, making the diagnosis difficult in the absence of specific diagnostic tests At present electromyography serves to distinguish the condition from hysteria on the one hand and paralytic poliomyelitis on the other It would be interesting to know whether cases diagnosed as poliomyelitis with spasm are not in reality examples of it

The fact that 11 cases came to light at one fever hospital last year during the period when poliomyelitis was prevalent suggests that the infection may have been widely scattered in the community Other London hospitals are also known to have had cases among their nurses, though none had an outbreak with the same "explosive" character as the Royal Free From last year's experience, and the presumption that many of the staff have acquired immunity, one might expect that the present outbreak there will be promptly checked Acquaintance with this disease, however, confirms its elusiveness, and probably most of the nurses and many of the domestic and clerical staffs have changed in the interval In the modern hospital, doctors seem to be the most stable section of the population

TREATMENT OF VOLKMANN'S CONTRACTURE

The stigma which was so long attached to Volkmann's contracture still sticks, though it is now sixteen years since Griffiths[1] made it clear that the condition is in fact due to traumatic arterial spasm and that the application of overtight plasters and splints is seldom more than a minor contributory cause Rarely does the surgeon have the opportunity of exposing the damaged artery and attempting to relieve the spasm before irreparable damage is done to muscles and possibly nerves, more often he is faced with the resulting paralysis and contracture The attack on this problem has recently been intensified and more radical methods of treatment have yielded gratifying results

For many years treatment was directed solely towards correcting the flexion deformity of the wrist and digits In its simplest form this consisted in applying some form of splint to stretch the contracted muscles slowly but forcibly Except in the milder cases, the deformity rapidly recurred after the splint was removed Various operations, such as the muscle slide operation of Max Page or some form of bone shortening, such as carpalectomy, were rather more successful But the contracture and the deformity it produces are merely signs of massive ischæmic necrosis of the affected muscles, and these methods of treatment could not be expected to restore their contractility At best the patient was enabled to take advantage of the trick action in which active dorsiflexion of the wrist naturally produces some degree of flexion of the digits

Recognising this defect of all previous operations, Parkes[2] took advantage of this trick action and restored a really useful range of flexion by transplanting one of the active extensors of the wrist into the tendons of flexor digitorum profundus, all the useless contracted tendons having previously been divided at a higher level to overcome the deformity A great advantage of this transplant is that the patient needs no re education, the transplanted unit naturally contracts with the remaining dorsiflexors of the wrist, and the summation of the effects of the trick action and the action of the transplant gives a good range of flexion of the fingers

Seddon[3] has recently described an even more radical method in which the aim is to excise the whole of the infarct before restoring flexion by transplanting an active tendon This enables him to assess the degree of ischæmic damage to the median nerve, and when spontaneous recovery seems unlikely he excises the whole of the ischæmic portion Continuity is then restored either by a free graft, using that portion of the median nerve at the elbow which originally innervated the long flexor muscles of the forearm, or, in cases where both median and ulnar nerves have suffered extensive ischæmic damage, by an ulnar-to median pedicle graft, as described by St Clair Strange[4]

There has undoubtedly been a considerable advance in the treatment of this crippling deformity Naturally each patient requires careful assessment before operation, the timing of which is also important In the less severe cases where the deep forearm muscles bear the brunt of the ischæmia, the remaining function in the flexor sublimis can be transferred to the tendons of flexor profundus after division of the profundus at a higher level When all the flexors are involved but the median nerve is functioning, Parkes's method gives an excellent result so long as the

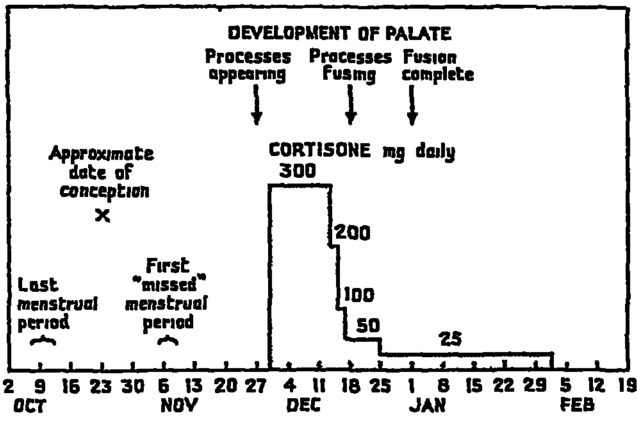

Fig 1—Relation of cortisone treatment to pregnancy

mg b d, the continuing amenorrhœa being attributed to cortisone therapy

Follow up—When she attended as an outpatient on Feb 2, her uterus was enlarged to a size equivalent to that of an 18 week pregnancy Cortisone was discontinued, the total dose received being 6 05 g The patient remained in good health, with a normal blood pressure throughout the remainder of her pregnancy, the steatorrhœa improving both clinically and biochemically On July 30, 2 weeks past the expected date of delivery, she was readmitted for medical induction of labour This was unsuccessful, and since some doubt existed about the maturity of the fœtus she was discharged On Aug 11 she was readmitted in labour and delivered spontaneously of a fresh stillborn male baby The placenta was relatively small and weighed 8 oz—i e, a thirteenth of the weight of the baby

The baby appeared to be full term on macroscopical and radiological examination Weight 6 lb 8 oz No external abnormalities The palate (fig 2) had a large postalveolar cleft The lungs were collapsed, and the trachea and main bronchi contained thick meconium stained mucus Several small hæmorrhages were present beneath the visceral pleura and epicardium No further abnormalities were found, and the appearances suggested that death resulted from intra uterine anoxia

Experimental Evidence

Congenital malformations have received increasing attention during the past twenty years This has led to the concept that the process of normal development is influenced by both genetic and environmental factors, but, since the effects of the latter may simulate those of the former, it is often impossible to distinguish between them General reviews relating to this have been presented by Gruenwald (1947), Warkany (1947), Boyd and Hamilton (1950), and Giroud (1954)

Experimental evidence of the teratogenic effect of cortisone was first reported by Baxter and Fraser (1950) Using the house mouse, an animal in which "spontaneous" cleft palate (without hare lip) is rare, they administered cortisone to pregnant females and produced cleft palates in 44% of the offspring The prevalence of cleft palate in the offspring of treated mothers varied between 4% and 100% in different *strains of mice, the result* depended partly on the genotype of the mother and partly on that of the fœtus (Fraser and Fainstat 1951, Fraser et al 1954)

Fainstat (1954) treated pregnant rabbits with intramuscular cortisone and reported 17 cleft palates among 35 embryos from the 7 treated does In the rabbit also, the spontaneous occurrence of cleft palate without hare lip is apparently rare

It is apparent from these papers that the outcome of pregnancy in the treated animals is related to the dosage of cortisone, the period of gestation during which it is administered, and the genotypes of the mother and the fœtus The highest prevalence of cleft palate in the offspring was obtained when treatment with cortisone was begun a few days before the time of normal closure of the palatal processes, thereby suggesting that it interferes with the development of the palate

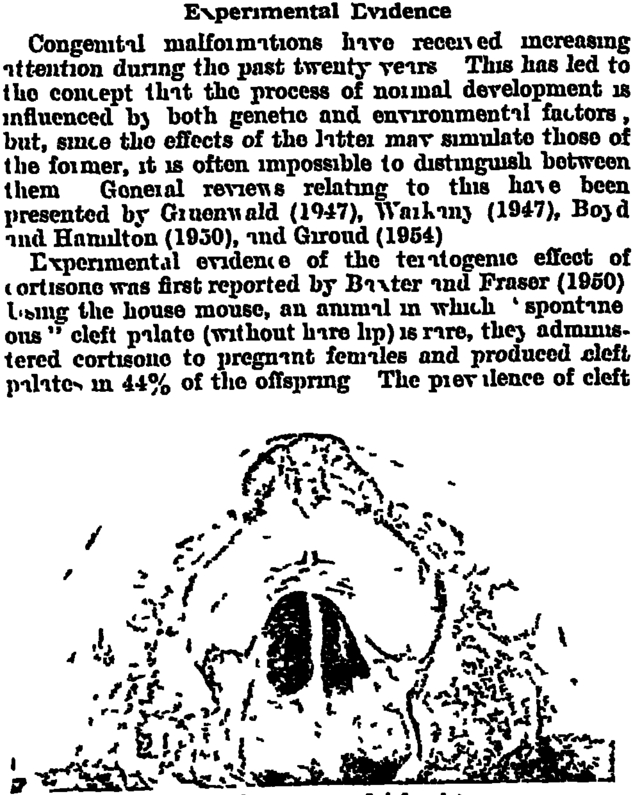

Fig 2—Inferior aspect of cleft palate

Discussion

Three aspects of this problem require careful consideration (1) was the cleft palate reported here merely a chance finding?, (2) are the conclusions of the experiments on laboratory animals applicable to man?, and (3) in view of the increasing use of cortisone, why have congenital defects in human babies not been reported before?

A study of the series of clefts of the lip and palate reported from Denmark by Fogh Anderson (1946) and from Britain by Oldfield (1950) and Holdsworth (1954) reveals a prevalence varying from 1 600 to 1 1000 live births Of these 25–36% are isolated clefts of the palate, which were noted to be more common in female babies in two of the three reported series In Denmark hereditary factors were present in 30–40% of the total group, but in British cases they were only present in 11% and 18% Fogh Andersen (1946) stated that isolated clefts of the palate seldom appeared to have a hereditary basis These observations are inconclusive in determining the ætiology of the cleft palate in the present case

If the results of the experiments on laboratory animals are applicable to man, to get a cleft palate it would be necessary to administer an effective dose of cortisone immediately before the time of closure of the palatal processes In man these processes appear about the 45th day, and closure is normally complete by the 12th week In the present case it appears reasonable to assume that fertilisation took place on or about Oct 22, hence cortisone therapy began on the 38th day of pregnancy and continued throughout the time during which the palatal processes would normally have been fusing Though it is accepted that there are objections to a comparison of the dosage used in animals with that used in man, on the basis of a milligramme of cortisone per kilogramme of body weight, it has been suggested (Greenhill 1952) that an equivalent dose for a human being would be 4–8 g of cortisone Our patient received a total of 6 g, of which 4 g was given between the presumed 38th and 52nd days of pregnancy

There are many reports of the use of cortisone in human pregnancy, but in almost every instance it was administered after the 8th week and in a dosage considerably smaller than that used in the present case These doses may not have been large enough to produce congenital abnormalities Wells (1953) treated 29 cases of nausea and vomiting in early pregnancy with cortisone Of the 27 women followed up 24 gave birth to normal babies, and the remaining 3 to babies with congenital malformations other than cleft palate, none of which were attributed to the treatment

Conclusion

Though there is no justification for attributing the cleft palate reported here to the administration of cortisone to the mother in early pregnancy, it appears extensors of the wrist have full function and the tendon transplant can be kept well away from the area of severe ischæmia. In the worst cases with necrosis of the median nerve, Seddon's more radical methods offer the best hope of restoring recovery.

There remains the problem of the paralysis of the intrinsic muscles of the hand which may result from ischæmia of the ulnar nerve. Parkes is at present working on a method in which the inert tendons of flexor sublimis are used to act as check ligaments to minimise clawing of the fingers, and this may well prove to be a further useful contribution to the reconstructive surgery of established Volkmann's contracture.

ADRENOCORTICAL FUNCTION IN PHYSIOLOGICAL STRESS

PATHOLOGISTS have long known that changes in certain organs are common to a great many different diseases. Conspicuous examples are the atrophy of the thymus and the loss of adrenal lipids in children dying of septic and toxic diseases. The first to formulate a definite non-specific syndrome common to many diseases was probably Widal,[1] who described the "hæmoclastic crises" characterised by a postprandial leucopenia in diseases of the liver; he compared it with the "shock-like" drop in circulating leucocytes after injection of foreign protein and with similar phenomena in paroxysmal hæmoglobinuria and allergic and infectious diseases. A more detailed description of unspecific hæmatological changes came from the work of Arneth[2] and particularly of Schilling,[3] who established the biological leucocyte curve common to many infectious diseases. He distinguished three phases: (1) the neutrophil battle phase with neutrophil shift to the left and eosinopenia; (2) the monocytic phase of resistance; and (3) the lymphocytic eosinophilic phase of recovery. About the same time, a series of investigations originated in the observation that various acute febrile illnesses had a beneficial effect on entirely unrelated pathological processes. Two familiar examples are the regression of Hodgkin's disease and nephrosis during measles. Weichardt[4] studied the effects of parenteral administration of proteins and he referred to a general activation of the protoplasm including its enzymes.[5] Wagner Jauregg reported remissions in general paralysis of the insane after injections of tuberculin, and this observation led to malaria therapy.

There followed Selye's work[6,7] on the alarm reaction, the general adaptation syndrome, and diseases of adaptation resulting from the derailment of a physiological defence mechanism. He claimed that a great many very different stresses produced in laboratory animals an involution of the thymico-lymphatic apparatus and an enlargement of the adrenal cortex, with an increased discharge of cortical hormones in addition to liberation of adrenaline. Since cortical extracts, cortisone, or corticotrophin (A.C.T.H.) also produce atrophy of the thymus and lymphatic tissues, and since hypophysectomised animals show neither enlargement of adrenals nor thymico-lymphatic atrophy when exposed to stress, these observations suggested that the pituitary received the primary stimulus and that the adrenal was the central organ of the *general adaptation syndrome*. Much time was devoted to histological and histochemical changes in the adrenals in unspecific stress and attempts were made to assess the functional state of the adrenal cortex in such conditions. Selye's ideas stimulated thorough and often critical investigations, particularly of the histological and histochemical aspects.[8–13] Much work has been done on the distribution and identification of cortical lipids, phosphatases, and dehydrogenases. But the attempts to identify ketosteroids were sternly criticised by Boscott and Mandl.[14] Depletion of the adrenal cortex of lipids was made the basis for conclusions no less dogmatic than the opposite assumption of old pathologists that adrenals with abundant lipids were hyperactive and those with depleted lipids were exhausted. Depletion of lipids may be due to rapid discharge, to exhaustion of enzymes necessary for their synthesis, or even to irreparable degeneration. There are hopes that simultaneous estimation of lipids and of enzymes of the Krebs cycle, such as succinic dehydrogenase, may lead to more conclusive results.[15]

In clinical investigations, too much significance has been attached to the Thorn test, on the assumption that lymphopenia and eosinopenia is clear evidence of increased cortical function. It has been shown, however, that adrenaline produces eosinopenia in adrenalectomised animals sustained by cortisone.[16] Moreover, a stressor which evokes discharge of adrenaline will influence the white cell picture by vasoconstriction and by direct action on the target organs—two effects which do not run parallel.[17] Similarly, increased urinary output of 17-ketosteroids need not indicate adrenal hyperfunction, since, in the adult male at least, their main source is the testis. *Investigations are therefore welcome in which the* effects of stress have been carefully compared with those of corticotrophin. Such investigations have been carried out for several years in Boston by a large team of workers, including clinicians, endocrinologists, pathologists, psychiatrists, and statisticians.[18–20] Members of a college boat racing crew were studied during a four-mile race, during the intensive preparation and test trials, and on control days. The subjects examined also included coxswains, a crew manager, students presenting a clinical case for the first time, candidates for a PH.D. degree, and a mixed professional group during the showing of a documentary film of primitive tribal rites. The inquiry also included an untrained man who took part in a three-hour 17-mile run, 4 patients with Addison's disease during exercise, and a patient with bilateral adrenal cortical hyperplasia. Eosinophil counts and estimations of 17-ketosteroid, 17-hydroxycorticoid, and uropepsin excretion[21] were carried out. Psychological tests included the Rorschach test and thematic tests in which the imaginative response to pictures is evaluated. In most cases the physical and psychological stress resulted in a drop in the eosinophil count, and an increase in the urinary excretion of 17-hydroxycorticoids, 17-ketosteroids, and uropepsin; but in several cases there was a discrepancy between the drop in the eosinophil count and the rise in urinary 17-hydroxycorticoids. Loss in the sweat was suspected but excluded. Sometimes the drop in eosinophils was the only positive test. The excretion of 17-hydroxycorticoids was increased during the race, but not on practice days which involved an equal amount of muscular activity. It seems that, in trained persons at least, psychological factors are more important in cortical stimulation than muscular work.

thyroidism have appeared. The high, poorly-sustained gland uptake of I^{131} and the high protein-bound-I^{131} values are similar to those which we have previously reported in this family group. The findings in this child suggest even more strongly than in our previous cases that a considerable proportion of the plasma iodine (26·8%) is di-iodotyrosine. Chemical examination suggests that 60·8% of the iodine in the urine is di-iodotyrosine. Paper chromatography of a butanol extract of the urine confirms that di-iodotyrosine is being excreted in substantial amounts. These findings support the view that the members of our tinker family have the same enzymatic defect as that described by Stanbury et al.[3] in their most recent publication.

We agree with you that sporadic cretinism with goitre is genetically determined.[4] Study of the family tree of our patients, fuller details of which we hope shortly to publish, convinces us that the pedigree satisfies the criteria of the simple recessive inheritance of a single gene.

ETHYL BISCOUMACETATE AS INHIBITOR OF SICKLING

Sir,—Last year Griffiths[8] reported inhibition of the sickling phenomenon, in a patient with the sickle-cell trait, after administration of ethyl biscoumacetate ('Tromexan'). Since then we have had the opportunity of treating four such patients with ethyl biscoumacetate. Sickling of the red blood-cells was not altered in any way during or up to three days after cessation of the ethyl biscoumacetate therapy. We feel that it is unlikely that the phenomenon noted by Griffiths was related to administration of this drug.

UNFAIR TO SURGERY

Sir,—I hope you will allow us to comment briefly upon your annotation on Regional Ileitis (Dec. 17). In the course of this you say: "Resection cannot therefore be regarded as a cure", and again: "It therefore seems that surgery has no place in cure. . ." Doubtless with the dictum so ably enunciated by the Bellman[9] in mind ("I have said it thrice: what I tell you three times is true") you add yet once more: "but while surgery can offer no cure . . ." In spite of Dr. Cooke's beautifully presented lecture,[10] and realising that two cases are of little significance, we nevertheless feel that these are worth a short mention.

Case 1.—In 1932, at the age of 20, a medical student began to have attacks of epigastric pain and vomiting accompanied by loss of weight and some malaise. This was the same year in which Crohn[11] and others first described regional ileitis. Four years later Mr. Harold Wilson operated upon this young man and found that the terminal three feet or so of his ileum was involved by a condition which he thought to be tuberculous but which was later correctly identified by Dr. A. H. T. Robb-Smith as regional ileitis. The affected ileum and part of the ascending colon were resected. Nineteen years later this patient is as fit as a fiddle.

Case 2.—In 1941, at the age of 28, another medical student noticed lassitude, much loss of weight, and generalised abdominal pain. Two years later symptoms of subacute intestinal obstruction were apparent. This patient was by now house-surgeon to Mr. Wilson who, with the help of his surgical chief assistant (case 1), removed some two feet of almost completely obstructed ileum and a severely diseased cæcum. Thirteen years later this patient is as fit as another fiddle.

Your annotation dwells in detail on the steatorrhœa and electrolytic imbalance which accompanies ileitis, but neither of these patients suffers now from disordered bowel function or abnormal stools. Furthermore they can claim, like the Oysters[12] that "some of us are out of breath and all of us are fat." Both are satisfied that their disease is cured and both believe that surgery cured it.

But then, of course, we were the patients.

RUPTURED UMBILICAL HERNIA

Sir,—Until I read Dr. de Glanville's interesting article (Dec. 24) on a case of ruptured umbilical hernia I had no idea that the condition was so rare. So many umbilical herniæ in elderly people have little more than skin and integument covering them that such a disaster has always seemed to me to be more than a possibility. Dr. de Glanville found only five reported cases; to his case therefore I would like to add a seventh.

In 1951 an elderly Italian, in the course of a bout of coughing, felt that "something had gone wrong" with the umbilical hernia which had not so far troubled him through the three decades of its existence. On examining himself he was astonished, but apparently not very alarmed, to find his intestines lying freely exposed under his shirt. He called a taxi and was taken to the Italian Hospital. He was not shocked and seemed a little surprised at the necessity for operation.

After a careful cleansing of the extruded bowel (which included many feet of small intestine and the sigmoid colon) I darned the umbilical hernial orifice with floss silk. The reduction of the sigmoid colon proved a little difficult as it was greatly distended and appeared to be the site of a chronic volvulus; this may well have been a factor in the final rupture. The repair was scarcely more satisfactory than the condition of the tissues on which it had to be done, but nevertheless the old man made a good recovery.

By an odd coincidence this man was readmitted to hospital last week with intestinal obstruction in his recurrent umbilical hernia. At operation the bowel was found to be gangrenous and perforated with peritonitis involving the general peritoneal cavity as well as an incarcerated sac. The perforation in the bowel was converted into a colostomy, and the general peritoneal cavity drained. The patient's general condition was poor, but a second and equally unsatisfactory repair was attempted. He has survived operation but his ultimate recovery this time is problematical.

London, W.1

Geoffrey E. Parker.

"MUNCHAUSEN'S SYNDROME"

Sir,—If a tallish man, aged 26, with a right facial palsy, a recent right endaural incision, perhaps with thread sutures still in position, old right postauricular scars and a "crew" hair-cut should seek medical assistance there may be a doctor chancing to read this who will be glad of the following information.

Such a patient was admitted under my care on Dec. 4, 1955, complaining of right parietal headache, a right facial palsy of two weeks' standing, and right aural discharge. He said that he had had three mastoid operations on the right ear within the past eighteen months. In the ward he was found to have a temperature swinging between 99 and 101°F, and as he was extremely intolerant to the suggestion of having a lumbar puncture, having had 11 previously with much pain, I persuaded him to have an anæsthetic to carry out this essential investigation. The cerebrospinal fluid was found to contain 11 white blood-cells per c.mm. and 110 mg. of protein per 100 ml. In view of this and the persistence of the temperature and the temporal headache, and in the absence of sufficient signs to indicate a brain abscess, I explored the right mastoid in the expectation of finding pus in a dead labyrinth, cochlea function having been shown to be absent.

At operation it was found that a most thorough radical mastoidectomy had been already performed. There was no pus in relation to the widely exposed dura mater of posterior and middle cranial fossæ, nor on lifting the dura towards the apex of the petrous bone was any evidence of infection discovered. Partial removal of the promontory of the inner ear revealed only fibrous tissue. The endaural incision was, therefore, closed with thread sutures.

From a chance remark our suspicions were raised about the validity of the pyrexia, and inquiries revealed that during the past eighteen months a patient answering his description had been in numerous hospitals (in London, Plymouth, and Dublin), and as late as Nov 24 he had had a craniotomy at a hospital in London on account of a suspected lesion of the cerebellum or right temporal lobe None had been found

On Dec 14, the day after the mastoid operation described, the patient took his own discharge in hasty preference to investigation by a psychiatrist

I shall be very glad indeed to help any colleague confronted with this unusual case

S R MAWSON

AN UNWANTED EFFECT OF B C G VACCINATION

SIR,—I have recently started my second year of B C G vaccinating in Swansea Like many other local health authorities we are vaccinating school children in the 13–14-year age group who are Mantoux-negative and have a clear chest radiograph, and whose parents have consented

A slight alteration in administrative arrangements has given an opportunity of repeating the Mantoux test in a sample of children who were vaccinated in 1954 The reversion-rate seems likely to be very small I have, however, seen one or two further examples of an unusual, if trivial, consequence of the vaccination procedure which I first observed in 1954 A few children who received B C G vaccination then have a small, red, persisting papule at the site of the post-vaccination Mantoux test

The only explanation I can find is the use for a few sessions of P P D solution with a phosphate buffer which caused considerable local pain on injection This particular P P D aroused complaints from other parts of the country and was replaced by a solution buffered with borax and boric acid, which gives rise to no pain Possibly the former P P D solution, as well as causing pain, produced the papule

The papule is not a notable blemish on even the fairest skin, but I should be interested to read of other vaccinators who have encountered this phenomenon or of an alternative explanation of it

CERVICAL VERTIGO

SIR,—I was pleased to see that cervical joint lesions have been recognised as a cause of vertigo Following a report by Mr Terence Cawthorne,[1] I pointed out[2] that 15% of his patients gave a history of injury He believed that the injury damaged the labyrinth, but I was of the opinion that the head injury jarred the cervical joints, and said that there was no doubt at all that manipulation of the cervical joints could relieve vertigo in suitable cases

In each of the cases described by Dr Ryan and Dr Cope (Dec 31) there had been some form of trauma, and in each there was a latent period after injury before the vertigo developed I suggest that during this latent period adhesions form round the apophyseal joints, and that it is stretching of these adhesions with the setting up of abnormal afferent impulses there that disturbs the neck reflexes and causes vertigo Accurate analysis of the intervertebral-joint movements in these cases would probably have revealed the exact site of the joint lesion

In my experience manipulation of the neck has been most effective in relieving vertigo, and I have noticed that local joint fixations have been released by manipulation I suggest that the traction which appeared to cause vertigo in the cases mentioned would stretch the adhesions but not break them, and thereby merely irritate the joint lesion

While a collar may be helpful in some cases, particularly in the early acute phase, it is my experience that manipulation accurately applied to the faulty joint will achieve much quicker results

London, W 1

ALAN STODDARD

THALASSÆMIA IN A SCOTTISH FAMILY

SIR,—There are Scottish families whose members have served with distinction in the Navy for generations They may be said to have "thalassæmia" in that they have the sea in their blood But no educated man would suspect that thalassæmia is now supposed to mean anæmia characterised by jaundice, splenomegaly, reticulocytosis, decreased erythrocytic fragility, and a mongoloid appearance[1]

Let us drop this illiterate monstrosity before it defiles medical literature What is wrong with "Cooley's anæmia"?

London, W 1

HENEAGE OGILVIE

DANGER—CLINICIANS AT WORK

SIR,—On reading the first issue of your esteemed journal in this Leap Year, I am somewhat disturbed by the conclusions in three of the main papers

On p 5, Dr Doll and his colleagues assure us that, in spite of the century old custom, dieting with bland foods does not increase the rate of healing of peptic ulcers

On p 9, Mr Sharrard and Dr Knowelden discuss the ineffectiveness of splinting in the treatment of abductor paralysis at the shoulder—an accepted treatment for many years In fact, we are told it may even be harmful

Even worse, on p 19 Dr Brodie and his colleagues state that the general carrier rate of *staphylococci* is *doubled* as a result of admission to hospital, and thus hospital infection is due to resistant strains This may partly explain that dangerous condition—pseudomembranous enterocolitis

When I was a student I faithfully believed my teachers that we had entered a scientific age and that the days of cupping, bleeding, and purging were over, and Semmelweis might rest peacefully in his grave as his task was done

I am not suggesting that we abolish clinicians They are a necessary evil, but I would suggest, as a New Year resolution, that all who are interested in preventive medicine (I do not refer exclusively to those in the public health service) should do all in their power to make it unnecessary for clinicians to practise their therapeutic arts

WERTHEIM'S HYSTERECTOMY

SIR,—It will soon be five years since Mr John Howkins described in your columns his conception of a synchronous combined abdominovaginal hysterectomy,[2] and it is interesting to speculate upon the comparative unpopularity of this procedure today Probably many gynæcologists have no colleague of adequate experience who would be available to share the operative responsibility at a time convenient to both Possibly a theatre staff trained in conventional gynæcological procedures might find difficulty in making the abdominal and vaginal fields simultaneously equally accessible It is certain that many surgeons whose operations are preceded by radiotherapy consider total vaginectomy quite unnecessary

In the last few months a modified technique of extended vagino abdominal hysterectomy has been elaborated

With the patient in lithotomy position a circular incision is made as far up the vagina as seems desirable in each individual case, at least half the canal being removed The dissection then proceeds as described by Mr Howkins until bladder and rectum are freed from the cervix and the paramctrium is

AN OUTBREAK OF TYPHOID FEVER ASSOCIATED WITH CANNED OX-TONGUE

W. R. M. COUPER
M.B. Edin., D.P.H.
DISTRICT MEDICAL OFFICER, NORTH RIDING OF YORKSHIRE

KENNETH W. NEWELL
M.B. N.Z., D.P.H.
EPIDEMIOLOGIST, EPIDEMIOLOGICAL RESEARCH LABORATORY, CENTRAL PUBLIC HEALTH LABORATORY, LONDON

DONALD J. H. PAYNE
M.B. Lond., Dip. Bact.
DIRECTOR, PUBLIC HEALTH LABORATORY, NORTHALLERTON, YORKS

In December, 1954, an outbreak of typhoid fever, in which the vehicle of infection was apparently a can of ox-tongue occurred in a market town with a population of 4150 in the North Riding of Yorkshire. Because of the presence of influenza virus B infection in the area and because of the treatment of the patients with chloramphenicol in the belief that they had influenza in the earliest cases typhoid fever was not diagnosed until more than five weeks after the onset of symptoms.

The Cases

33 persons, 21 females and 12 males aged 14–76, were affected. 30 had symptoms of typhoid fever, 2 were symptomless excreters, and 1, who had no illness and from whom *Salmonella typhi* was not isolated had agglutinins suggesting recent typhoid infection. Of the 30 clinical cases 10 were confirmed by the isolation of the epidemic strain—*Salm. typhi* Vi phage type E1—16 were confirmed serologically, 2 had a clinical illness like typhoid fever but were not investigated in the laboratory, and 2 had an illness similar to that of many of the other patients and lived in houses where there were confirmed cases of typhoid fever, but their serological findings were not typical, and *Salm. typhi* was not isolated from their urine or fæces.

23 cases were primary and 4 secondary. 3 cases may have been infected primarily or secondarily.

The presence of typhoid-H agglutinins in persons with no history of inoculation with T.A.B. vaccine was considered to indicate infection with *Salm. typhi*. All those included had typhoid-H titres of 1/160 or higher, though the first serological examinations were in most instances made about nine weeks after the onset of symptoms. Typhoid-H titrations are not usually considered to be of diagnostic value in persons who have been inoculated with T.A.B. vaccine (Felix 1924) because of the possibility of anamnestic rises in H titres during non-specific fevers. The typhoid-O response, however, is regarded as specific though it is impossible to distinguish typhoid from paratyphoid-B fever by this titration, because of the somatic factor 12 which is common to the two organisms and produces agglutinins in both diseases. For the sake of completeness typhoid-H as well as typhoid O titres are given in the following details of 5 persons who had had T.A.B. inoculation:

	Typhoid H titre	*Typhoid O titre*
3 patients	1/640	1/320
1 patient	1/320 and 1/160	1/320 and 1/30 ten days between examinations
1 patient	1/50 and 1/10	1/10 and 1/250 fifteen days between examinations

The following is a typical case:

A man aged 26, felt unwell on Dec. 17 and went to bed next day with shivering and headache. During the following week he had pyrexia, prostration, and insomnia. On Dec. 22 he had severe epistaxis, and a general practitioner was called. The patient's temperature was then 101°F but he was comfortable and had no abdominal pain. He was treated with analgesics, and his temperature returned to normal. On Dec. 27 his temperature was again raised, he complained of pains in his chest, and he became delirious. Chloramphenicol 0.5 g. six-hourly was given from Dec. 29 for five days. He then felt much better, and his temperature became normal but he felt weak and still needed rest in bed on Feb. 1 when his serum gave titres of typhoid H 1/640, typhoid-O 1/640. He had never had T.A.B. vaccine, and eight fæcal and four urine specimens taken between Feb. 3 and Feb. 15 were negative.

4 patients died. 2 of them were a man and his wife both aged more than 70 who died before the outbreak was recognised and had undergone no laboratory investigation. The man had had abdominal pain, distension, vomiting, and constipation, and died at stool thirteen days after the onset of his illness. The woman who had a previous hemiplegia, developed headache, prostration, and delirium, and died after a severe intestinal hæmorrhage the day after her husband. A woman who nursed the couple and a man who ate food prepared in the house both developed typhoid fever. The other 2 fatal cases were confirmed bacteriologically: 1 was a woman, aged 72 with chronic congestive heart-failure, who died two months after the onset of the typhoid fever. The other was a man, aged 53, who died seven weeks after the onset of his illness following an operation for intestinal perforation.

Date of Onset of Symptoms

Although typhoid fever was not suspected until the fourth week in January, the first patients became ill on Dec. 17. Between that date and Dec. 31 all 23 cases considered to have been primary had developed symptoms (see table). Infections with influenza virus B which were confirmed serologically, were prevalent just before and during the early part of the typhoid outbreak, and nearly all of the first 23 patients with typhoid fever were treated with chloramphenicol for five to ten days as cases of severe influenza. It was only when some relapsed after treatment and a complete laboratory investigation was made that typhoid fever was diagnosed.

DATES OF ONSET OF THE 23 PRIMARY CASES

—	Dates of onset (December 1954)														
	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
No. of cases	4	5	3	5	2	1	1	1	—	—	—	—	—	—	1

Affected Households

The 25 persons thought to have been primarily infected—23 with symptoms and 2 without symptoms—came from sixteen households. 1 of the patients arrived in the town on Dec. 2, another was there only from Dec. 8 to Dec. 16, and a 3rd was there only from Dec. 11 to Dec. 15. It therefore seemed probable that infection took place in the first two weeks of December and the dates of onset suggested that the patients might all have been infected on the same day.

Fourteen households were supplied with chlorinated water from the town supply, and two from another chlorinated source. The sixteen households obtained milk from five different retailers, and there was no pooling or holding of milk among the suppliers. There were no common supplies of butcher's meat, cakes, ice-cream, or bread. Groceries were obtained from two shops in the market place. The only common factor found was that in all sixteen households tongue or ham had been purchased from the same grocery shop in the first two weeks of December. Eight households bought tongue only, seven bought tongue and ham, and one ham only.

A family who bought tongue and ham on Dec. 11 clearly remembered details of the purchase. The wife was a part-time employee at the grocery shop concerned,

ENDEAVOUR

Man's inventions and achievements
During his long sojourn on the Earth
Give us glimpses of a spectrum
At once colourful and marvellous
Skill and dexterity are begotten
Of truth and beauty;
Out of science he fashions harness for the elements;
And in the arid desert
He builds a living city
That reaches upwards to the stars
But man's exertions merge into the sublime
When, on the wings of the morning
He soars into the spacious canopy of God's universe
Into the ultra-violet zone of intellect—
Where colours fade
And things unseen
Are the things eternal

Letter from the 15-year-old daughter of a community hygienist to her mother, dated June 16, 2056

My dear Mummy,

I had a lovely day for my birthday I think Teacher must have known it was my birthday for after lunch (we had acorns and medlar cordial) we were taken to the London Museum It was wonderful First we were shown over the ancient part which we were told was in existence over a hundred years ago and then we were taken round the new People's Palace of Health and Culture You may have read that it was opened last month by the Secretary of State for Stratospheric Affairs

What we all liked best were the working models of the funny old underground railways It seems that just before they gave them up in 1988 in favour of nuclear propelled monorails they used to have white carriages and red carriages You see, that was in the days when people smoked tobacco and some people thought that it caused cancer of the lung and other people who liked smoking didn't, so the ones who didn't mind getting cancer went in the red (for danger) carriages and smoked and the ones that didn't want to get cancer went in the white ones which were labelled ' non-cancers " Of course they didn't know in those days that the underlying cause of cancer was a deficiency of guava jelly and that tobacco only hastened their end because they were going to die of some form of cancer anyway ten or twenty years later Actually the N.P monorails just came in time because all Londoners were found to be suffering from chronic emphysema, as well as cortical hypoxia, caisson disease and claustrophobia for spending so much of their time underground.

The guide was most interesting, for he was born in 1907 and was just old enough to remember the Cigarette Age, and he had actually smoked them himself He said they were horrid and a thoroughly bad habit Daddy will be amused to hear that doctors were the worst offenders, and things got so bad in 1975 that only a quarter of them didn't get cancer of the lung and survived to sign up the death certificates of the other three quarters We saw the famous Nottinghill collection of ashtrays which the old man bequeathed to the nation He was the last man to drink port and also the last man to be made a peer Some of the ashtrays he had to pay ever such a lot of money for at Christie's We also saw some amusing things called petrol lighters They caused cancer of the antrum and singed eyebrows

The guide said that when he was our age he would have been surprised to be taken round by a man aged 149, but they hadn't learnt then about the " peace of mind factor without which people used to grow old Incidentally it was once called ' the tortoise factor " because it was first isolated from the chyle of a tortoise He said that in the fifties of last century people used to do extraordinary things and get awful diseases through eating butter and margarine and meat and canned peas, and drinking milk contaminated with strontium 90 and tea, and washing their knives and forks and plates and also their undies in detergents Apparently their bread was dreadful too, and they were always having rows about it in Parliament and in the medical journals He said that for a long time Americans and Britons used to die of coronary thrombosis and everyone thought it was due to worry and eating butter and trying to get through traffic jams in a hurry (automobiles had to keep on the ground then), till someone remembered that the two nations had something else in common—*they used to eat eggs for breakfast*—just think of it, cholesterol ! No wonder their coronary arteries were all choked up Why a child would know better than that today

By the way we saw the National Collection of Alcoholic Drinks including whisky and sherry and gin in their original 20th century bottles Apparently before the passing of the Wine Restriction Act of 1990 (which followed the Abolition of Drinking Spirits Act of 1987—Teacher says I'm jolly good at history) you could buy all sorts of nasty gastric erosives and you didn't have to produce a certificate of gastronomic proficiency and submit the menu to the Ministry of Dietetics like we do now to get a bottle of wine In those days you could murder wine with bad cooking if you wanted to

I thought there was something else to tell you ; Lenina and John have been granted their permissive Licence of Procreation They said they had no trouble with the Psychiatric Board but there was a good deal of bother with the geneticist wallahs because some of Lenina's genes didn't tie up properly with his blood group but any way they passed them in the end I am so pleased about this because she is so deserving of the honour of motherhood

Remember I shall be home for the weekend after next because great-great granny is taking me on a botanical hike in the Himalayas When you make up the picnic hamper don't forget the unsaturated fats Until Friday week, your loving daughter,

Helen

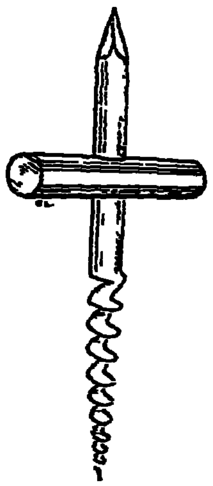
NEW INVENTIONS

A Useful Brain Biopsy Burr

Attempts to obtain brain-tissue with a hammer and chisel have not proved entirely satisfactory for routine investigation in the living subject Great advances in the technique came with the introduction of the Jones brain-biopsy burr Consisting of a spiral cutting-edge mounted at right angles to the handle, this instrument made it possible to extract adequate biopsy samples by a simple manœuvre of rotation pressure and brisk traction In the hands of Smith frequent resort to the state of the plantar responses proved an essential feature of the procedure and a sharp metal spike was therefore added to the handle This modification suffers from the disadvantage that, in order to apply the spike to the sole of the foot, the burr must be removed from the skull which is a pity



In this new modification (see accompanying figure) of the Smith modification of the Jones burr, the spike is rendered detachable by simply screwing it on and off Thus the plantar responses may be elicited without having to dislodge the entire instrument from the skull each time and it has been used in a small number of volunteers with the minimum of complications Since the spike is used solely for the feet, sterility is neither necessary nor desirable. Moreover if damaged or broken it can be replaced at a fraction of the total cost Owing to its ready detachability, the spike has also proved of value in numerous other uses about the theatre and it is ideal for prising open tin lids for anæsthetists coffee.

It is a pleasure to acknowledge the help of the research division of the Deathly Soundproofing Corporation Co., Ltd., without whose coöperation this work would not have been possible Grateful thanks are also due to Sister C[illegible] for permission to use the theatre, to the governor of [illegible] Scrubs for special facilities, and to the [illegible] for one piece of advice The instrument is manufactured by the Publican Bottle Accessories Co Potheen, C[illegible] extensors of the wrist have full function and the tendon transplant can be kept well away from the area of severe ischæmia. In the worst cases with necrosis of the median nerve, Seddon's more radical methods offer the best hope of restoring recovery.

There remains the problem of the paralysis of the intrinsic muscles of the hand which may result from ischæmia of the ulnar nerve. Parkes is at present working on a method in which the inert tendons of flexor sublimis are used to act as check ligaments to minimise clawing of the fingers, and this may well prove to be a further useful contribution to the reconstructive surgery of established Volkmann's contracture.

ADRENOCORTICAL FUNCTION IN PHYSIOLOGICAL STRESS

PATHOLOGISTS have long known that changes in certain organs are common to a great many different diseases. Conspicuous examples are the atrophy of the thymus and the loss of adrenal lipids in children dying of septic and toxic diseases. The first to formulate a definite non-specific syndrome common to many diseases was probably Widal,[1] who described the "hæmoclastic crises" characterised by a postprandial leucopenia in diseases of the liver; he compared it with the "shock-like" drop in circulating leucocytes after injection of foreign protein and with similar phenomena in paroxysmal hæmoglobinuria and allergic and infectious diseases. A more detailed description of unspecific hæmatological changes came from the work of Arneth[2] and particularly of Schilling,[3] who established the biological leucocyte curve common to many infectious diseases. He distinguished three phases: (1) the neutrophil battle phase with neutrophil shift to the left and eosinopenia; (2) the monocytic phase of resistance; and (3) the lymphocytic eosinophilic phase of recovery. About the same time, a series of investigations originated in the observation that various acute febrile illnesses had a beneficial effect on entirely unrelated pathological processes. Two familiar examples are the regression of Hodgkin's disease and nephrosis during measles. Weichardt[4] studied the effects of parenteral administration of proteins, and he referred to a general activation of the protoplasm including its enzymes.[5] Wagner Jauregg reported remissions in general paralysis of the insane after injections of tuberculin, and this observation led to malaria therapy.

There followed Selye's work[6,7] on the alarm reaction, the general adaptation syndrome, and diseases of adaptation resulting from the derailment of a physiological defence mechanism. He claimed that a great many very different stresses produced in laboratory animals an involution of the thymico-lymphatic apparatus and an enlargement of the adrenal cortex, with an increased discharge of cortical hormones in addition to liberation of adrenaline. Since cortical extracts, cortisone, or corticotrophin (A.C.T.H.) also produce atrophy of the thymus and lymphatic tissues, and since hypophysectomised animals show neither enlargement of adrenals nor thymico-lymphatic atrophy when exposed to stress, these observations suggested that the pituitary received the primary stimulus and that the adrenal was the central organ of the general adaptation syndrome. Much time was devoted to histological and histochemical changes in the adrenals in unspecific stress, and attempts were made to assess the functional state of the adrenal cortex in such conditions. Selye's ideas stimulated thorough and often critical investigations, particularly of the histological and histochemical aspects.[8–13] Much work has been done on the distribution and identification of cortical lipids, phosphatases, and dehydrogenases. But the attempts to identify ketosteroids were sternly criticised by Boscott and Mandl.[14] Depletion of the adrenal cortex of lipids was made the basis for conclusions no less dogmatic than the opposite assumption of old pathologists that adrenals with abundant lipids were hyperactive and those with depleted lipids were exhausted. Depletion of lipids may be due to rapid discharge, to exhaustion of enzymes necessary for their synthesis, or even to irreparable degeneration. There are hopes that simultaneous estimation of lipids and of enzymes of the Krebs cycle, such as succinic dehydrogenase, may lead to more conclusive results.[15]

In clinical investigations, too much significance has been attached to the Thorn test, on the assumption that lymphopenia and eosinopenia is clear evidence of increased cortical function. It has been shown, however, that adrenaline produces eosinopenia in adrenalectomised animals sustained by cortisone.[16] Moreover, a stressor which evokes discharge of adrenaline will influence the white-cell picture by vasoconstriction and by direct action on the target organs—two effects which do not run parallel.[17] Similarly, increased urinary output of 17-ketosteroids need not indicate adrenal hyperfunction since, in the adult male at least, their main source is the testis. Investigations are therefore welcome in which the effects of stress have been carefully compared with those of corticotrophin. Such investigations have been carried out for several years in Boston by a large team of workers, including clinicians, endocrinologists, pathologists, psychiatrists, and statisticians.[18–20] Members of a college boat-racing crew were studied during a four-mile race, during the intensive preparation and test trials, and on control days. The subjects examined also included coxswains, a crew manager, students presenting a clinical case for the first time, candidates for a PH.D. degree, and a mixed professional group during the showing of a documentary film of primitive tribal rites. The inquiry also included an untrained man who took part in a three-hour 17-mile run, 4 patients with Addison's disease during exercise, and a patient with bilateral adrenal cortical hyperplasia. Eosinophil counts and estimations of 17-ketosteroid, 17-hydroxycorticoid, and uropepsin excretion[21] were carried out. Psychological tests included the Rorschach test and thematic tests in which the imaginative response to pictures is evaluated. In most cases the physical and psychological stress resulted in a drop in the eosinophil count, and an increase in the urinary excretion of 17-hydroxycorticoids, 17-ketosteroids, and uropepsin; but in several cases there was a discrepancy between the drop in the eosinophil count and the rise in urinary 17-hydroxycorticoids. Loss in the sweat was suspected but excluded. Sometimes the drop in eosinophils was the only positive test. The excretion of 17-hydroxycorticoids was increased during the race but not on practice days which involved an equal amount of muscular activity. It seems that, in trained persons at least, psychological factors are more important in cortical stimulation than muscular work.

Letters to the Editor

RADIATION HAZARDS

SIR,—The Medical Research Council report is of great interest, and many of its results must be accepted In particular it seems that the genetic damage caused by experimental nuclear explosions so far is much less than that caused by diagnostic radiology in economically advanced countries This is probably so for the world as a whole since the British figures are fairly typical for some 400 millions of human beings, though in the absence of protection from houses the danger from fall-out in the tropics may often exceed that in Britain, sometimes by a factor as high as 7, the value given on p 57 of the report

But the report seems to suffer from two defects, one of presentation and one of calculation In its table 1 D (p 93) the extra births of phenylketonurics among a generation of 20 million due to a doubling of the mutation rate are given as 5 But the total in all subsequent generations, supposing the population of England to remain steady, would be 500, and the total for the world on the same assumption, would be about 60 times this figure, or 30,000 Phenylketonuria accounts for about 1% of severe mental defect, but not all mental defect is genetically determined If two thirds were genetically determined, a doubling of the mutation rate for one generation would probably lead to the birth of about 2 million mental defectives, and also, in my opinion, of a somewhat larger number of physically defective children and a good many more abortions and stillbirths

The report estimates the increase of radiation to human gonads from test explosions as less than 1% (p 39) or less than 0 03r per generation, and the doubling dose as 30 to 80r (p 45) or 10 to 27 times the natural dose So if tests continue at the present level during one generation, their total effect would be to produce only about 2000 mental defectives or less However this may be, I think that a figure of 5 might prove unduly reassuring to a casual reader, even if a figure of 2 million is regarded as too alarming

But I believe that these figures are too low, for the following reason[1,2] Before any atomic bombs had been exploded, I calculated the probable mutation-rates corresponding to existing frequencies of congenital abnormalities The calculation was therefore unaffected by any emotions concerning nuclear warfare If a recessive gene for a character such as phenylketonuria has a frequency of 0 5% in gametes (as assumed in the report) and no phenylketonurics breed, this means that, apart from inbreeding, 0 5% of such genes meet with other similar genes per generation, so such a gene has an average "life" of 200 generations between its appearance by mutation and its elimination by natural selection But inbreeding accounts for a good many cases Of Munro's[3] 47 families containing phenylketonurics three parental pairs were first cousins two were more distant relatives and very likely another five or more were still more distantly related, the two genes which cooperated to produce an idiot or imbecile being due to the same original mutation

If, in fact 11 or 12 of Munro's families (say, 25%) were from consanguineous parents the mean "life" of such a recessive gene is reduced to 160 generations But in the middle ages and earlier inbreeding was far more prevalent than today Most people lived in villages and married neighbours Thus recessive genes were eliminated much more rapidly than today and a higher mutation-rate was needed to balance this elimination Owing to the long "life" of these genes the present gene frequency was effectively determined many centuries ago It is difficult to guess at the intensity of inbreeding in mediæval England I have assumed a figure well below that found for a Jewish community in South Germany, but above that of nineteenth century European peasantries On this basis one can very roughly calculate the mutation rate, and it turns out to be about 2 6 times that given in the report, perhaps more For rarer genes the correction is greater Thus I think that the total number of mental defectives produced by a doubling of the mutation rate during one generation would be nearer 8 million than 2 million, and might well exceed 10 million Since it is stated in the M R C report (p 90) that the principles on which mutation rates can be indirectly estimated were laid down by myself in 1932, I think that my own subsequent work, which increased the estimates by a considerable factor, might have been taken into consideration I am aware that they were stated in a rather abstract and mathematical form For this reason I have given them here in as simple words as I could achieve I may add that when the correction is made, the doubling dose for the gene for phenylketonuria if it is as sensitive as the average of 7 genes investigated by Russell[4] in mice, becomes about 36r, which is in accordance with the findings of the report (p 45) The detailed calculations will be published elsewhere

I wish to emphasise the importance of human inbreeding for another reason It is proposed to compare the frequencies of several abnormalities in different areas, in the hope of discovering or disproving a mutagenic effect of radioactive substances in the soil In the case of rare recessive conditions inbreeding in some rural areas may be expected to have a very large effect Since, on the whole, inbreeding may be expected to be higher in the more radioactive areas of Britain (e g , West Cornwall and Aberdeen) than in the country as a whole, rare recessive conditions will also be common And this might well lead to an overestimation of the mutagenic effect of radioactive minerals For this reason it is my conviction that such a survey would be a waste of public money, and what is even more serious, of the skill of the men and women who undertake it

It must also be remembered that the human doubling doses of radiation *may* be higher than for most other animals, on account of the great length of human generations Thus a human generation is about sixty times as long as a mouse generation, and a man receives 60 times as much radiation per generation But the number of nuclear divisions per generation which may also provoke mutation, is not much greater in men than mice Hence radiation may be a relatively more important mutagenic agent in men than mice, and the doubling dose correspondingly lower If so the calculated effects must be multiplied by a further factor

BURNS AND SCALDS

SIR,—Your leader of May 19 and the letters from Dr Hall Smith (May 26) and Dr Leonard Colebrook (June 2) discuss the treatment to be carried out—in the home or in the surgery—of burns and scalds which are sufficiently superficial to justify non hospital treatment Dr Hall-Smith protests that your advocacy of an anti histamine ointment encourages the development of sensitisation eczemas Dr Colebrook upbraids you for neglecting the advice of Bull et al[5] to use topical penicillin Dr Hall Smith remarks that anti histamine ointment is fast replacing the topical antibiotics as the most potent cause of iatrogenic dermatitis Dr Colebrook denies that topical penicillin is likely to produce

Public Health

AN OUTBREAK OF TYPHOID FEVER ASSOCIATED WITH CANNED OX-TONGUE

W R M COUPER
M B Edin , D P H
DISTRICT MEDICAL OFFICER, NORTH RIDING OF YORKSHIRE

KENNETH W NEWELL
M.B N Z , D P H
EPIDEMIOLOGIST, EPIDEMIOLOGICAL RESEARCH LABORATORY, CENTRAL PUBLIC HEALTH LABORATORY, LONDON

DONALD J H PAYNE
M B Lond , Dip Bact
DIRECTOR, PUBLIC HEALTH LABORATORY, NORTHALLERTON, YORKS

IN December, 1954, an outbreak of typhoid fever, in which the vehicle of infection was apparently a can of ox-tongue, occurred in a market town with a population of 4150 in the North Riding of Yorkshire Because of the presence of influenza virus B infection in the area and because of the treatment of the patients with chloramphenicol in the belief that they had influenza, in the earliest cases typhoid fever was not diagnosed until more than five weeks after the onset of symptoms

The Cases

33 persons, 21 females and 12 males, aged 14–76, were affected 30 had symptoms of typhoid fever, 2 were symptomless excreters, and 1, who had no illness and from whom *Salmonella typhi* was not isolated, had agglutinins suggesting recent typhoid infection Of the 30 clinical cases 10 were confirmed by the isolation of the epidemic strain—*Salm typhi* Vi phage type El—16 were confirmed serologically, 2 had a clinical illness like typhoid fever but were not investigated in the laboratory, and 2 had an illness similar to that of many of the other patients and lived in houses where there were confirmed cases of typhoid fever, but their serological findings were not typical, and *Salm typhi* was not isolated from their urine or fæces

23 cases were primary and 4 secondary 3 cases may have been infected primarily or secondarily

The presence of typhoid-H agglutinins in persons with no history of inoculation with T A B vaccine was considered to indicate infection with *Salm typhi* All those included had typhoid H titres of 1/160 or higher, though the first serological examinations were in most instances made about nine weeks after the onset of symptoms Typhoid-H titrations are not usually considered to be of diagnostic value in persons who have been inoculated with T A B vaccine (Felix 1924) because of the possibility of anamnestic rises in H titres during non specific fevers The typhoid-O response, however, is regarded as specific, though it is impossible to distinguish typhoid from paratyphoid B fever by this titration, because of the somatic factor 12 which is *common* to the two organisms and produces agglutinins in both diseases For the sake of completeness typhoid-H as well as typhoid O titres are given in the following details of 5 persons who had had T A B inoculation

	Typhoid H titre	*Typhoid O titre*
3 patients	1/640	1/320
1 patient	1/320 and 1/160	1/320 and 1/80 ten days between examinations
1 patient	1/50 and 1/10	1/10 and 1/250 fifteen days between examinations

The following is a typical case

A man, aged 26, felt unwell on Dec 17 and went to bed next day with shivering and headache During the following week he had pyrexia, prostration, and insomnia On Dec 22 he had severe epistaxis, and a general practitioner was called The patient's temperature was then 101°F, but he was comfortable and had no abdominal pain He was treated with analgesics, and his temperature returned to normal On Dec 27 his temperature was again raised, he complained of pains in his chest, and he became delirious Chloramphenicol 0 5 g six hourly was given from Dec 29 for five days He then felt much better, and his temperature became normal, but he felt weak and still needed rest in bed on Feb 1, when his serum gave titres of typhoid H 1/640, typhoid O 1/640 He had never had T A B vaccine, and eight fæcal and four urine specimens taken between Feb 3 and Feb 15 were negative

4 patients died 2 of them were a man and his wife, both aged more than 70, who died before the outbreak was recognised and had undergone no laboratory investigation The man had had abdominal pain, distension, vomiting, and constipation, and died at stool thirteen days after the onset of his illness The woman, who had a previous hemiplegia, developed headache, prostration, and delirium, and died after a severe intestinal hæmorrhage the day after her husband A woman who nursed the couple and a man who ate food prepared in the house both developed typhoid fever The other 2 fatal cases were confirmed bacteriologically 1 was a woman, aged 72, with chronic congestive heart failure, who died *two* months after the onset of the typhoid fever The other was a man, aged 53, who died seven weeks after the onset of his illness following an operation for intestinal perforation

Date of Onset of Symptoms

Although typhoid fever was not suspected until the fourth week in January, the first patients became ill on Dec 17 Between that date and Dec 31 all 23 cases considered to have been primary had developed symptoms (see table) Infections with influenza virus B, which were confirmed serologically, were prevalent just before and during the early part of the typhoid outbreak, and nearly all of the first 23 patients with typhoid fever were treated with chloramphenicol for five to ten days as cases of severe influenza It was only when some *relapsed after* treatment and a complete laboratory investigation was made that typhoid fever was diagnosed

DATES OF ONSET OF THE 23 PRIMARY CASES

—	Dates of onset (December 1954)														
	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
No of cases	4	5	3	5	2	1	1	1	–	–	–	–	–	–	1

Affected Households

The 25 persons thought to have been primarily infected —23 with symptoms and 2 without symptoms—came from sixteen households 1 of the patients arrived in the town on Dec 2, another was there only from Dec 8 to Dec 16, and a 3rd was there only from Dec 11 to Dec 15 It therefore seemed probable that infection took place in the first two weeks of December, and the dates of onset suggested that the patients might all have been infected on the same day

Fourteen households were supplied with chlorinated water from the town supply, and two from another chlorinated source The sixteen households obtained milk from five different retailers, and there was *no* pooling or holding of milk among the suppliers There were no common supplies of butcher's meat, cakes, ice cream, or bread Groceries were obtained from two shops in the market place The only common *factor* found was that in all sixteen households tongue or ham had been purchased from the same grocery shop *in the* first two weeks of December Eight households bought tongue only, seven bought tongue and ham, and *one* ham only

A family who bought tongue and ham on Dec 11 clearly remembered details of the purchase The wife was a part-time employee at the grocery shop concerned, this sensitisation in more than insignificant numbers Here I think most dermatologists and many practitioners would differ But is Dr Hall-Smith's ointment (hydrocortisone and neomycin) itself above suspicion ?

I find it difficult to accept that 38% of the burns you consider suitable for treatment by the housewife or the general practitioner will become infected with hæmolytic streptococcus if they are not treated with penicillin cream , yet this is what Dr Colebrook would have us infer from his letter I believe he is trying to apply the results of studying the severe burns he saw at the Birmingham Accident Hospital to the more trivial ones seen on the practitioner s rounds, and I do not think one can safely do so

I have now been watching and treating the obviously superficial burn for ten years, and I am convinced (with Dr Hall Smith) that the risks of sensitisation to topical antibiotics are very real, and that they are not outweighed by the dangers of streptococcal invasion in this type of injury I have used anti histamine ointments and not seen any trouble so far—but I will heed his warning I will continue to clean these burns with cetrimide (' Cetavlon), to dry them, and cover them with tulle gras I will not be converted to topical antibiotics (having abandoned them) unless I see much more streptococcal invasion than I do at present I will arrange admission to hospital of the deeper burns, as soon as I suspect they *are* deep I will continue, I am sure, to make occasional mistakes, and to present a colleague, or my own ward, with a streptococcal wound —but not in 38% of cases And I will still be able to look the dermatologist in the eye

On reflection Dr Colebrook will probably agree that the prolongation of the old lady's disability was less likely to be due to early infection than to unrecognised full thickness damage, and unrecognised full-thickness damage brings its own infection with it Neither penicillin cream nor any other application would have done as much as a decision to send the case to hospital for early skin grafting If penicillin cream is called for every time the kettle is upset, it will do more harm than good

Sunderland   T G LOWDEN.

DETENTION OF THE MENTALLY HANDICAPPED

SIR,—Medical superintendents of hospitals for the mentally handicapped must be somewhat bewildered at the moment If they keep patients too long in hospitals they are criticised, and if they license them out they are liable to be accused of subjecting the general public to risks from violence

The question as to the suitability of a patient for release to the community is surely a matter for experienced medical superintendents who have had these patients under their continual observation

The high grade mental defective is probably quite able to perform remunerative tasks and may appear on the surface to be suitable for discharge Yet personal histories may reveal tendencies to persistent immorality, thieving, indecency and inability to conform to normal standards of living Instances of inability to cope and plan (typical of the high-grade *defective*) are well known , many of them are far happier in the institution atmosphere where their occupations and social activities are arranged for them Medical superintendents required to give evidence in courts of law have their hands tied and cannot reveal confidential case histories which might embarrass relatives , it is unfortunate that dispensers of the law are so ready to make comments and give views on superficial examination without specialised knowledge of the problem It is doubtless true that there have been cases of wrongful diagnosis and certification, but I suggest that such cases are few and that there is no need for panic measures

The recent circular of the Board of Control[1] has been viewed with concern by local authorities, who have always taken an impartial view of recommendations for discharge from institutions, since sooner or later they may have to provide further care and supervision for these cases I agree with the view expressed by the medical superintendent of a large hospital[2] that eighteen months is insufficient time in which to judge whether a patient is stable enough to be at large in the community

Fitness for discharge should be decided on the individual merits of each case One step that may help to solve the problem is the provision of sheltered day workshops, combined with residential hostels giving a certain amount of liberty coupled with kindly discipline and supervision

Z P FERNANDEZ
Chairman Leeds Mental Health
Services Subcommittee

PAIN IN PEPTIC ULCER

SIR —Your leading article of June 16 omitted one of the principal considerations It is clear that all pain is conditional upon the state of the higher levels of the brain Further, it has long been established that the movements and secretions of the stomach are adjusted by conditioned reflexes which pass through the cerebral cortex , and conditioned responses have been obtained from painful stimuli It is thus reasonable to suppose that there is a process of interaction between stomach and cortex—a supposition supported by the prominent rôle of psychological factors in peptic ulceration Account must therefore be taken of those changes which Pavlov showed to occur in the functional derangement of cortical cells, especially pathological inertia and the paradoxical phase

I venture to suggest that attempts to explain the pain of peptic ulcers mechanistically in terms of local factors alone do not correspond to the clinical problem On the other hand, a study of the local pathology in relation to the pathophysiology of conditioned reflexes might be more rewarding

Sheffield   C H FOGGITT

TUBERCULIN-TESTING OF SCHOOL-CHILDREN

SIR,—It is five years since MacDougall et al[3] reported the results of tuberculin-testing of school-children as a method of detecting sources of tuberculous infection Independently a similar scheme was started in Ipswich in 1950, and since then 752 children have been referred by the school medical service to the chest clinic for investigation 688 (91%) children and their families and other home contacts have been seen As a result 42 cases of tuberculosis, including 8 of active disease, have been discovered among the children, and 39 cases, including 6 of active disease, among the contacts This is not a great harvest compared with the results of others, but it has been a worth-while experience from which we would draw the following conclusions

1 The shorter the interval between the infection and the tuberculin testing the greater the likelihood of success At a residential school we discovered 4 active cases among 13 converters tested at an interval of a year

2 A very thorough search of all home contacts must be made At least 3 active cases came to us through other sources within a short time of the tuberculin testing of the children

3 All home contacts must be interviewed It is humiliating to discover the proportion of infections that can be traced to known sources (50–60%)

4 In an area where bovine infection has been recently present the results of testing can be most confusing, but with experience past and present bovine sources can be identified and fairly accurately dated

5 The tuberculin jelly test using flour paper, gives a high rate of false positives (20%) in 5 year old children compared with the Heaf multiple puncture or Mantoux tuberculin tests

[3] MacDougall I A Milhall J R Tattersall, W H *Med Offr*, 1951 86 253 *Brit med J* 1953 i 64

her duty was to make up orders for delivery Having a cold on Dec 10 she stayed in bed on Dec 11 and arranged for her mother to come from a neighbouring town and look after her from Dec 11 to Dec 15 On Dec 11 her husband bought the last $^1/_2$ lb of a can of unsliced tongue and some sliced ham The wife ate *all the ham but only tasted the tongue, which was eaten* by her husband and mother on Dec 11 and 12 Her husband and mother developed typhoid fever on Dec 17 and 20 respectively, while she was unaffected

The housewife who bought only ham bought it on Dec 11 She ordered $^1/_4$ lb of tongue, which was sliced with a knife, wrapped in grease proof paper, and weighed Meanwhile she found that ham was considerably cheaper than tongue and asked the grocer to give her $^1/_4$ lb of ham instead The ham was cut with the same knife It was eaten by 3 persons for lunch on the day it was bought 2 *of them ate a small amount and were* unaffected, but the 3rd, who ate most of it, developed typhoid fever twenty days later In this case there was an opportunity for contamination of the ham from the tongue by the use of the knife used for slicing both products

Tongue was bought every Saturday in December by nine households three bought it only on Saturday, Dec 11, and three bought it in the first two weeks in December but could not remember the exact date Tongue was therefore a common factor among all the patients but one, and this patient ate ham which may have been contaminated by a knife from the tongue The evidence suggested Dec 11 as the date of infection In some enteric fever outbreaks the occurrence of gastro enteritis soon after the time of infection helps to confirm the date of infection, but in this outbreak none of the affected persons had had any gastro intestinal illness in the four weeks preceding their enteric illness

The Ox-tongue

The tongue sold on Dec 11 came from one 6 lb can and was bought by a score or so of households, the average quantity purchased being about $^1/_4$ lb Typhoid fever developed in fifteen of these households The high proportion of affected households indicates that *the tongue must have been extensively contaminated*

The grocer was certain that tongue was never left over from one day to another, and that there was no possibility that tongue from a can opened on Dec 10 had been sold on Dec 11 The can sold on Dec 11 was opened in the shop on Dec 11 by the grocer and was of normal appearance taste, and odour It was the custom to slice part of the tongue on the bacon-slicing machine ready for the earlier customers, and this may have been done on this day The remainder was cut with a knife for each order The knife was also used for slicing ham and sometimes for cutting up packs of sausages, but sausages were usually sold packed, and on many Saturdays the knife was not used for sausages at all

Inquiries were made in the factories producing the ham and the sausages sold on Dec 11, but there were no findings to suggest that either of these foods was contaminated

The Food Handlers in the Shop

On Saturday, Dec 11 three men and one woman in the shop may have handled the tongue One man had been in France in 1914 but gave no history of a typhoid illness Serological and bacteriological tests on him and his family, including sewer swabs in the drains of his house, were negative In the case of another man, who had never been out of the country similar tests were negative The third man and the woman, his daughter, had eaten tongue but not ham from the shop for luncheon on Dec 11 Serological examination and the examination of this man s urine and fæces were negative His daughter however, became ill on Dec 17, went to bed on Dec 18, and next day had nausea, slight diarrhœa, thirst, insomnia, and rigors She was *treated with chloramphenicol* 0 5 g six hourly for ten days, her temperature became normal on Jan 3, 1955, and she was convalescent on Jan 9 She had never had T A B vaccine The agglutination titres of her serum on Feb 12 were typhoid H 1/640+, typhoid O < 1/10 Nine specimens of fæces and five of urine did not yield *Salm typhi* She is considered to have been a victim of the outbreak

The Can

All the evidence therefore suggested that the can was *contaminated before being opened in the shop* It was manufactured overseas and had been packed in June, 1954, and shipped in July It was of double seam soldered construction with cap and bridge The top collar and bottom of the can were double seamed on to the body flanges, which had been pre dipped in solder After double seaming heat had been applied to the seams to sweat the solder and to make a complete seal This method of construction reduced the risks of leakage to a minimum (T E Bashford, personal communication) However, small self sealing leakages can develop in a small proportion of such cans, and these leaks may allow the entry of a drop or two of fluid before resealing takes place (Townsend and Esty 1939, Braun 1953) In these circumstances no change may be noted in the partial vacuum in the can Leakage is most likely to take place when the cans are being cooled in water at the end of the canning process

The Canning Factory

The suspected can was one of 35,000 produced in the same factory in 1954, and no complaints about other cans were received by the producers The factory was situated on the bank of a deep fast flowing river Two supplies of water were used in the factory Both were drawn from below the surface of the river downstream from the outlet of the city sewage treatment plant One supply was filtered and chlorinated, and the other was untreated The untreated water was used for cooling the sealed cans in the retorts at the end of the canning process Treated water was used for all other operations in the factory After cooling, the cans were washed and then incubated at 92°F for fifteen days before they were labelled and shipped

If the can was contaminated in the factory, contamination probably took place during the cooling process, in which untreated water was used Sandiford (1954) isolated *Salm typhi* from a can of cream, but two hundred and twenty five other cans of the same batch were negative These cans had been cooled with water from a contaminated source However, with the type of can we have described, the possibility of leakage and the chances of examining a contaminated can are slight Only two unopened cans of tongue of the same batch were investigated They were examined by the Food Hygiene Laboratory and were found to be sterile The cans were sound

Discussion

The use of untreated river water for cooling cans in the retorts at the canning factory suggests, even though the cans were of double seamed construction, that the most probable source of contamination was in the factory *but there can be no certain proof of this* Sandiford (1954) showed that a similar state of affairs occurred with canned cream, but it must happen rarely A contaminated can might pass through the incubation test if it contained only non gas producing organisms, and *Salm typhi* does not produce gas The risk that a can will leak momentarily and in that moment will absorb an enteric non gas producing pathogen must be

6 *The incidence and annual rate of infection at specific age groups are valuable guides to the incidence of tuberculosis in the community*

In certain districts of Norway annual tuberculin-testing of school children has been practised for many years When conversions do occur which may be at intervals of three or four years, a diligent search, which rarely fails is made for the source

PASSION AND CONTROVERSY IN SCIENCE

SIR,—I was very interested to read Professor Polanyi's article (June 16) May I point out the slight error in the spelling of Prof J H van't Hoff's name ?

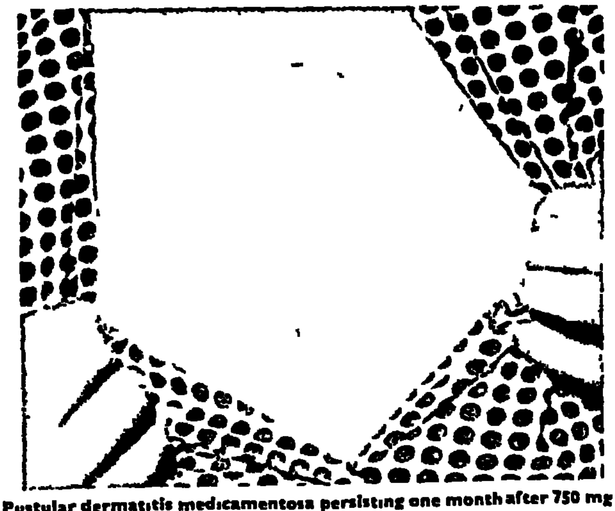
Westminster Hospital,
London S W 1
WALTER VAN'T HOFF

NOVOBIOCIN DERMATITIS

SIR,—Your comment of May 5 on Dr Pellerat's objection to restriction of new antibiotics induces me to suggest a generalisation that may serve to waive authoritarian action in this regard Although Dr Pellerat and a growing literature point to the emergence of resistant staphylococci, this is still being encountered chiefly in hospital populations (human and bacterial), and geneticists who are familiar with bacterial mutation are still reluctant to predict dangers to those undosed by antibiotics Strong independent opinion exists in this country that our gravest problem is in the indiscriminate use of penicillin and the "panallergenisation" to that antibiotic, an incidence that has been estimated at as high as 10%[1]

The wide use of the cationic mycin antibiotics (streptomycin the tetracyclines, and the carbomycins) did not result in comparable sensitisation True, these particular streptomyces derived antibiotics are potent contact dermal sensitisers, but appear to be weakly allergenic in the injectant or ingestant phase In fact certain hypersensitivity states have been treated by their administration[2] An explanation of this contrast between the cationic mycins and the anionic penicillin may be found in a rule pieced together from researches at the Canadian Red Cross Hospital in your country,[3] on the haptenic specificity of sulphated dextrans and those carried out in the United States on vaccine adjuvants[4] This rule has been enunciated as "macroanions enhance antigenicity (of an immunising substance), macrocations diminish it"[4]

Believing in the validity of this rule, I have prescribed the recently introduced anionic mycins for my own patients Several months ago, however, a housewife who had had a severe protracted urticarial reaction to penicillin ten years ago and who has had several bouts of recurrent purulent lymphadenitis, yielding in turn to the tetracyclines or carbomycins to which she is not sensitive was given the still experimental streptonivicin ('Albamycin') because her wound flora, a carbomycin oxytetracycline resistant staphylococcus was found markedly sensitive to it The third 500 mg dose was followed by such an intense generalised erythema and pruritus that it was discontinued and another, supposedly dissimilar, antibiotic (Pfizer PA 93) was obtained Naturally enough, since this is now known to be a novobiocin, the staphylococci proved susceptible in vitro Two weeks after the administration of the streptonivicin, PA 93 was given, on the second day it was evident that the abscess was reacting well but the patient poorly A maculopapular rash evolved over the next week, covering the scalp, cheeks, and torso finally becoming pustular in the fashion characteristic of a dermatitis medicamentosa One month after stopping PA 93 and two weeks after the eruption began to subside pustules were evident on the chest (see accompanying figure)



Pustular dermatitis medicamentosa persisting one month after 750 mg of oral novobiocin

Allergic dermatitis has just been reported[5] as a common complication of novobiocin So has urticaria[8] and other skin rashes[9] These have arisen during observations on small series and notes of caution have been sounded[10] These are perhaps not as yet convincing as to the validity of the rule about anionics[5] as applied to new antibiotics, but we should all dislike a repetition of the penicillin story

Laurelton Long Island

ROBERT D BARNARD

FIRST-AID MANUALS

SIR,—"First aid" must interest many of your readers, and yet it is surprising how seldom it is mentioned in your columns The quick and widespread reaction to the exchange on the "three quarter prone" position in head injuries[11] has prompted me to write this letter, in the hope that it may perhaps provoke a similar response

Those of us who are required by law to train and appoint first aid men in industry, or at least to supervise their training and appointment, are often in the embarrassing position of having to use a textbook whose teaching we regard as out of date and sometimes dangerous

The transport of unconscious patients on their backs has already been commented on, but this is surely less undesirable than the treatment of wounds advised in the latest (1951) edition of the St Andrew's Ambulance Association handbook, which says that "the edges should be gently sponged with some antiseptic solution such as diluted lysol, carbolic lotion (1 to 40), a weak solution of iodine (Liq Iodi Mitis B P 1932) or methylated spirit Some of the antiseptic used for cleansing the edges may be wrung out of a clean swab into the wound in order to complete the cleansing"

One feels that even Ambroise Paré would have disagreed with this, and yet it has continued to appear through seventeen editions

This is perhaps the worst of several passages in this particular manual which should have been altered long ago In the light of modern work on "surgical shock" and the improvement in the technique of accident surgery, passages in all the current textbooks need revision Furthermore I suggest that the revision should be supervised by people competent to assess

infinitesimal, and complete proof of its occurrence is almost impossible to obtain because only one in some thousands of cans is likely to be affected On general principles, however, it seems unwise for canners to use potentially contaminated water for their cooling processes

In the past twenty years there have been four outbreaks of typhoid fever associated with meat

In 1938 there were two such outbreaks, each affecting seventeen to twenty households (Ministry of Health 1938) Both were connected with grocery shops selling cooked canned meats, and the vehicle was thought to have been food, but no particular food was suspected In one shop the staff were negative bacteriologically and serologically, and in the other a girl who did the cleaning had a high content of antibody in her serum, but there was no evidence that she was a carrier

In April, 1948, an outbreak due to *Salm typhi* Vi phage type E1 at Crowthorne, investigated by Moore (1949), affected 41 persons The vehicle was thought to have been canned corned beef, and no carrier, symptomless excreter, or other source of contamination of the meat after the can was opened was found

Peters and Clutterbuck (1942) described a typhoid outbreak in Glasgow where 35 persons were affected and where meat was suspected of being the vehicle of infection No particular meat was common to all the primary cases, but the shop sold a high proportion of canned and processed meats A month after the suspected date of infection the butcher became ill with typhoid fever

Summary

An outbreak of typhoid fever due to *Salm typhi* Vi phage type E1, affecting 33 persons, is described Except for 1 woman, who ate ham which seems to have been secondarily contaminated, the primary cases were in patients who had eaten ox-tongue from one 6 lb can

The can of tongue was probably contaminated in the factory, after processing by sewage-polluted river-water used for cooling

The outbreak was unrecognised for five weeks because of a simultaneous outbreak of influenza B and the wide use of chloramphenicol

We wish to thank Dr E S Anderson and the staff of the Central Enteric Reference Laboratory and Bureau for Vi phage typing, Dr H G M Smith, of Bradford, for the influenza complement fixation tests, Dr Betty Hobbs of the Food Hygiene Laboratory, for the examination of food and water, Mr T E Bashford, of the Metal Box Company, for the examination of cans, Dr N J Hessian, of Yearsley Bridge Hospital, for details of his cases and Dr Kenneth Froome, of Scarborough Hospital, for some bacteriological results

DETERGENTS

A committee was appointed three years ago by the Minister of Housing and Local Government to examine and report on the effects of the increasing use of synthetic detergents and to make any recommendations that seem desirable with particular reference to the functioning of the public health services" Its report[1] contains a wealth of technical information which will be useful in the management of public waterworks and sewage-disposal plants, and it also covers many aspects of the problem which are of topical popular interest

The use of these household washing powders does not seem to have led to any significant increase in the incidence of dermatitis in housewives and laundry-workers Even in normal concentrations, however, they are capable of causing dermatitis in the susceptible and the risks are increased if they are not used in a sensible way Similarly they can have a deleterious effect on certain types of domestic plumbing If the housewife could strike a balance between sales resistance and casually extravagant use of detergents, a lot of interests at the other end of the sewer would feel much less anxiety

When crockery is slipped, without rinsing, from the foaming sink to the labour saving drying-rack, some traces of synthetic detergent inevitably remain to be swallowed with the next meal Whether this is harmful, and if so how the risk compares with those attached to cigarettes, diesel fumes, radioactive fall out, and the bizarre chemicals nowadays sprayed on our crops, remains to be discovered The committee says that long-term study is needed to see whether there are any ill effects

The production of massive foam at sewage-works is more than an embarrassment to the operators and a detriment to the purification process, the sewage-contaminated foam is liable to be picked up by the wind and blown across the countryside, which is not only unpleasant but a danger to public health Foaming extends into many of our main rivers and adds fresh hazards to the life of fish, which are already battling (for survival and oxygen) with sewage and industrial wastes When the same river becomes the public water-supply to downstream communities, the problem returns to the housewife

A majority of the committee fear that conditions may deteriorate and recommend the Government to consider whether control powers should be prepared in advance Four members, however, contend that the difficulties are being exaggerated, and hold that in any case the public health authorities ought to be clever enough to find the remedy Unfortunately the report does not disclose whether or not the four optimists happened by any chance to be the four representatives of the trade interests involved We like to know such things.

---

WESTERN EUROPEAN UNION

As a result of administrative arrangements which have just come into force, the member States of Western European Union now form a single territory for health control of sea and air traffic, thus extending the scheme operated by the five-power Brussels Treaty Organisation.

Under the new arrangements, health control regulations at airports no longer apply to aircraft coming from any of the seven countries of the Union, and the maritime declaration of health is no longer required from vessels of member countries plying only between those ports of the seven countries included in the scheme

An information exchange service has been organised so that the health authorities in member countries can keep in constant touch and can supply each other with information about all disease covered by international health regulations, or any epidemiological incident which would be of interest to the other countries

OCCUPATION CENTRES FOR THE MENTALLY DEFECTIVE

"The nurturing and training of mentally defective children in occupation centres is one of the most important and useful activities of a local health authority" Dr R W Elliott, medical officer of health for Bolton, expresses this view in his report for 1955 But, he adds Bolton's centre deals only with those up to the age of sixteen, and there is an overwhelming need for the centre to be extended so that all age-groups can be constantly guided and trained, to prevent social deterioration

All the excellent training which has been given before the age of sixteen years is completely nullified if at that age they have to leave us and become once more flotsam tossed about on the sea of life " the value of the advice offered from the points of view of ease of teaching practical application to the recently injured, and conformation to the requirements of the receiving hospital For this purpose I suggest the appointment of a committee composed of industrial medical officers and practising surgeons experienced in the treatment of accidents

Folkestone, W

F I CAIRD

MEDICAL EDUCATION

SIR,—Most essays on "medical education" excite the profession's interest, and I hope I have sympathy in airing a disappointment that Dr Ellis (June 2 and 9) should review so competently in his first article and then drift into platitude with his second He knows well what is wrong but has obtained little satisfaction by arguing himself back to "essential steps"

I suggest that the foundation fault is contained in his title The word "education" is by tradition limited to the developing adolescent mind and would be better avoided for any process applied over the age of 21 Thus, "further education" is really "further information," "postgraduate education" is "postgraduate revision," and medical education is a technical training—no more, no less

I ask readers to imagine what would happen if other professions adopted our attitude What kind of a man would a lawyer be, if he began his studies at 16 ? Or a priest ? Surely, better doctors would be produced by a shorter but very intensive and resident course, to be given to minds of proved general ability, and not to be commenced before the age of 20 or 21

Manchester

PHENYLBUTAZONE IN THE TREATMENT OF PROLAPSED INTERVERTEBRAL DISC

SIR,—I have read Dr Steer's valuable letter (June 16) in which he reports favourably on the treatment of prolapsed intervertebral discs with oral phenylbutazone

For the past $2^1/_2$ years I have treated such cases with this drug, and I am now preparing a detailed account of my experiences Approximately twenty-five patients have been given this drug either orally or by injection and the results compared with the previous twenty five cases treated by conventional methods

At first 600 mg of phenylbutazone by mouth was given daily for a week, after which the dose was reduced to 300 mg daily for as long as necessary I found that, although initially most of the cases responded satisfactorily, some showed a tendency to relapse or took a long time to recover During the past 6 months I have been more successful with intramuscular injections of 600 mg every third day for 6 weeks All those receiving the drug in this way left hospital within 10 days and continued to receive the injections from the district nurse In all the patients the relief from pain was rapid and the condition was usually cured by the end of the 6 week period In one instance an operation which had been advised for relief of pain of three years' duration has been avoided

It can be concluded therefore that this method of treatment may be superior to those in present use, but lengthy controlled clinical trials are necessary to establish its true value

Dudley Road Hospital

R O GILLHESPY

ANÆMIA IN PREGNANCY

SIR,—In your leader of June 2, the possible need to supplement dietary iron in pregnant women is considered entirely in terms of hæmoglobin, as though the only metabolic rôle of iron in the body was to provide part of the hæmoglobin molecule Furthermore no differentiation is made between nullipara and multipara Changes in the observed values for mean corpuscular hæmoglobin concentration and hæmoglobin mass may result from depletion of the iron store of the body, but neither is a measure of the size of this store There is no satisfactory way of measuring this in man at present

Surely the question of supplementary iron in pregnancy should be related to the problems of whether the mother, at her first menses after pregnancy and lactation, has a total body-iron content as great as when she conceived as a nullipara, and of whether her iron stores are replenished by the time she conceives again

There is little experimental evidence on this aspect of iron metabolism, but observations on rats by Widdowson and McCance[1] give a hint that the iron stores of a woman might still be depleted at her first post-pregnancy menses Such depletion might be prevented by supplementary iron during pregnancy

FOOD-POISONING AND DETERGENTS

SIR,—To combat the constantly rising incidence of food-poisoning and other infectious gastro intestinal complaints, the newly introduced Food Hygiene Regulations aim at improving the cleanliness of food-handling premises and the personal hygiene of food-handlers These requirements will cost the catering trade large sums Is there any certainty that they will reduce the incidence of these conditions ?

These diseases have become more prevalent in the past ten years despite great efforts by health departments in raising standards of personal hygiene in food-handlers and improvements in equipment methods, and cleanliness in food handling premises It is therefore unlikely that any material benefit will accrue from further efforts in these directions

If, after all the attention given over the past ten years to personal hygiene and cleanliness in food premises and even homes, the incidence of food borne *infections* is still increasing, it suggests to me that we are *not* attacking the problem at all and some other factor or factors must be involved In an effort to find other possible contributory factors it is worth considering what other changes have occurred in our way of life simultaneously with the increased incidence of food poisoning, and one stands out clearly —namely, the introduction of powerful, non bactericidal, synthetic detergents as a substitute for soap and their widespread use over the past ten years in homes and particularly in catering establishments

Is there a connection between the use of detergents and the increase in food poisoning ? Because of the widespread use of detergents for cleansing crockery, and the difficulty even with special care and attention of removing every trace of these, we must all be ingesting small amounts of detergent every day from our eating and drinking utensils especially when the more usual perfunctory methods of washing up are employed Detergents lower surface tension and can thus presumably affect cell permeability In solution they are excellent solvents and could presumably interfere with the normal protective mechanism of the gut lining, thus facilitating absorption of toxins and even the penetration of the mucosa by bacteria

Is it possible that the distribution among the community of the food poisoning organisms is unchanged and that before the introduction of powerful detergents we obtained relative natural immunity by the ingestion of small doses of organisms with which our normal protective mechanism could cope and also that small doses of ingested food poisoning toxins did not penetrate the gut-lining in sufficient quantity to give symptoms ? Such a possibility is not referred to by the

The Casualty Department

III A COMPREHENSIVE ACCIDENT SERVICE*

T G Lowden
B M Oxfd, F R C S
CONSULTING SURGEON, SUNDERLAND GROUP HOSPITALS

THE previous articles have described how the reception of emergencies, the disposal of accident cases, and the treatment of diverse minor conditions whose only common feature is that they are ambulant, are gathered into one department of the hospital This association has grown fortuitously, mainly because the arrival of all these patients is unpremeditated, but partly also because the disposal of accidents is only now, and only to a limited extent, being separated from the disposal of other emergency cases

Most of the country is so populated that only a few large cities can *support a system* where *all accident cases*, major and minor, can be dealt with at a centre whose periphery has a conveniently short radius Many industrial areas of 150,000–300,000 inhabitants cannot afford to provide for themselves a comprehensive system with fracture clinics, general surgical wards, head injury and burns units, and a staff to give a 24-hour cover The problem cannot be solved by making the largest casualty department the centre and closing down the rest, because this would reject very many of the minor injuries The question arises, on the other hand, whether *it is necessary* for every hospital to have a complete casualty department, and whether a redistribution of its three *main* functions could not make for greater efficiency and improved clinical results

If the medical and surgical emergencies which are to be considered for admission are assessed by the inpatient staff, their reception and early treatment pass at once into the hands of those who will follow their definitive treatment In many hospitals this system is already in operation, and the casualty officer's function is often confined to informing the R S O or R M O of their arrival In very large hospitals admissions are so frequent that it is an advantage to have someone whose main duty is to receive them, but in smaller ones there seems *to* be *no* valid objection to a system where the inpatient houseman is *called to see the case* he *will very soon* have to examine anyway, and there would be advantages *in* him carrying out examinations in the privacy of an admission room instead of after admission to the ward Putting responsibility for these cases upon the senior resident staff of the receiving hospital, and for accident cases on the accident service, would distribute among a number of doctors a medicolegal responsibility which is becoming too much for a single junior to bear

More of the "sorting-house" work can be avoided, if cases are referred direct to their special clinics instead of through the casualty department Radiological diagnoses should be made in the X ray department, general-practitioner work should be referred to the family doctor (now that everyone has a doctor), minor specialist procedures in such departments as E N T and skins should be done in the departments concerned

If an accident service could be organised in areas with a twenty mile radius, most of the remaining casualty work in all the related hospitals and clinics could be associated with it *under centralised supervision* but without bringing every patient to the centre itself

The Outposts

A perfect accident service starts at the accident itself, and a system of outposts, closely associated with a central hospital, would avoid calling every *minor* case to the centre Many such outposts in the industrial medical service, the medical units of nationalised industries, the school medical service, and the out patient departments or casualty rooms of the smaller hospitals have an independent existence already If the treatment of thousands of cases seen in these units can be integrated with the casualty department in a central hospital, a great step forward will have been made—and at the same time a mechanism will have been created for the more rapid and accurate reference of major accidents to their proper place of treatment

Those who have acquired extensive experience in the management of acute injuries would be the first to agree that orthopædic problems play much less part in it than is generally supposed The treatment of shock and of burns, the care of multiple injuries (especially the association of head injuries with injuries to other parts), problems of infection, plastic surgery, and special anæsthetic technique require an accident service that can call upon a team rather than an individual It is important *that an early decision should be made on whether* such a team is likely to be wanted The periphery of a casualty service must be capable of making such a decision with a high degree of reliability All parts of it should have a clear idea of the type of definitive treatment likely to be given at the centre, so that first aid, transport, and what has been called "second aid," are in line with the treatment the patient will ultimately receive

In this conception many of the smaller casualty departments, after being relieved of much of their responsibilities for the reception of inpatients and disposal of outpatients will cease to be part of the hospital in which they are housed They will become representatives of the accident service, and fulfil a function similar to other accident service outposts in large industrial concerns They will treat those cases which can be dealt with on the spot and refer those which require attention at the centre Their equipment can then be simplified, and in particular it will not be necessary for them to maintain outpatient operating theatres On the other hand, their facilities for administering first aid and shock therapy, and for organising rapid reference of major accident cases must be considerably improved They will be in constant communication with the main casualty department at the accident *centre They will always have power to admit* cases to the hospital where they are situated if it is felt that further travelling will be dangerous for the patient

The Centre

The central casualty department can cover an area of a thousand square miles It needs consultant surgeons and must be able to provide a day and-night medical cover It also needs enough doctors for one to visit each of the outposts daily Its establishment must include clerical assistance and the services of an adequate bacteriological laboratory It will have complete control of a short stay ward, and X *ray* facilities devoted primarily to its own needs It will have first call on the services of an anæsthetist It will be situated in the same hospital as the inpatient accommodation for the accident service, and will work as *part of that* service Its medical staff will be in constant touch with the emergency bed bureau and the other receiving hospitals of the area It will act as an information centre for all questions on the admission and disposal of urgent cases, its doctors will also be coordinating officers, and its senior doctor on duty will be in charge of casualty services

NOT OXFORD

SIR,—Many other Oxford men will join with me in applauding the initiative of the distinguished band of Cambridge medical men who, as reported in your last issue, realised the error of their ways just in time and took their degrees in the University of Oxford.

As a traditionalist, however, I feel I must protest against certain departures from precedent. No notice of a congregation on June 7 was given, and we were thus deprived of the opportunity of attending and welcoming our professional brethren appropriately. No witnesses can be found, nor has any mention of the conferment of these degrees appeared in the *O. U. Gazette*. Can it be that the silent Roman Emperors outside the Sheldonian were the sole spectators of some secret nocturnal ceremony?

Most deplorable of all was the use of English in the proceedings. Can the banal "By proxy" compare with the euphonious syllables of "In absentia"? One can only surmise that the vice-chancellor sanctioned this departure from traditional practice as a special concession, well knowing that Cambridge men would be untutored in the liberal arts.

Finally, Sir, what of the future? Are the lemmings on the move?

Westminster Medical School
London, S.W.1
ANDREW SHERRINGTON

*** We regret that last week (p. 1021) graduates of the University of Cambridge on whom the degrees of M.D. and M.B. had been conferred were shown as having gained the D.M. and B.M. of the University of Oxford. Otherwise our announcement was, we hope, correct. An amended notice will be found on p. 1078.—ED. L.

METHYLTESTOSTERONE

SIR,—Oral methyltestosterone has been used in clinical practice since its introduction by Foss in 1939,[1] both for its anabolic and for its androgen effects. It was not until 1947 that Werner[2] suggested that its use might occasionally be associated with jaundice. Other reports followed.[3-5]

The hepatic lesion found in cases of jaundice following methyltestosterone therapy was not associated with the laboratory findings usual with severe parenchymal damage or biliary obstruction: the cephalin flocculation reaction was negative, the serum-alkaline-phosphatase only moderately elevated, and the serum-bilirubin increased. Werner thought it improbable that methyltestosterone was a markedly hepatotoxic agent, since the syndrome was rare, despite the widespread use of this hormone. Further, in two patients who had recovered, renewed administration of this methylated compound failed to reproduce jaundice.

Since testosterone has not been so implicated, some pharmaceutical literature has given this as a reason in favour of sublingual or sublabial tablets of testosterone. Though testosterone when given orally is ineffective, owing to deactivation by the liver, the makers and others claim that given by the sublabial route it is as effective as parenterally administered esters.

Methyltestosterone on the other hand is effective both when swallowed and when absorbed sublabially, although it is slightly more efficient by the latter route.[6] It would seem, therefore, that methyltestosterone is less wasteful, as some of the hormone from the sublabial tablet of testosterone is bound to be swallowed in the saliva, particularly from the sublingual site. The metabolism of these two hormones is indeed different in that methyltestosterone (*a*) increases creatinuria and (*b*) does not increase the 17-ketosteroids. Although not directly related to the problem, it is perhaps of incidental interest that Lloyd-Thomas and Sherlock[7] used methyltestosterone to relieve the distressing pruritus of obstructive jaundice.

In a fairly extensive use of methyltestosterone, with doses ranging from 5 mg. daily to 150 mg. daily over long periods, we do not happen to have come across a case of jaundice. Since for practical purposes it would be a pity to omit the use of methyltestosterone, we should like to know whether any physicians in this country have noted jaundice which they attributed to methyltestosterone therapy.

ELUTION AND MICRO-ESTIMATION OF 5-H.I.A.A.

SIR,—The new colorimetric method of Udenfriend et al.[8] for the quantitative estimation of urinary 5-hydroxyindole-acetic acid (5-H.I.A.A.) is based on the older Gerngross reaction with 1-nitroso-2-naphthol and is simpler but less specific. It is, moreover, liable to serious error if "metabolic" keto acids are not completely removed with 2 : 4-dinitrophenylhydrazine, before the final extraction. Further, in all methods involving extraction if the extraction time, if quoted, is not strictly adhered to, quantitative results will not be obtained. These inherent weaknesses in the Udenfriend method can be overcome if the urine containing pathological amounts of 5-H.I.A.A. is directly applied to the paper for chromatographic separation and estimation. In normal urines, however, where the concentration of 5-H.I.A.A. is much less (1 to 5 µg. per ml.), it is still necessary to extract the 5-H.I.A.A. with ether, and evaporate to dryness in vacuo. The quantitative estimation of 5-H.I.A.A. by means of one-dimensional paper chromatography depends on a clear-cut separation of the spot, especially if an elution method is used; and whether the total colour in the spot can be quantitatively determined by photometric evaluation of the spot area and intensity, or by elution followed by colorimetric estimation; and whether Beer's law holds for the colour reaction employed and for the subsequent elution.

A semi-quantitative method for the estimation of 5-H.I.A.A. can also be used by assessing visually the amounts of 5-H.I.A.A. contained in the spots as regards area and intensity of colour of the spot given by the urine and spots obtained with standard amounts of 5-H.I.A.A. This method could be used in the clinical sideroom. But I am not aware of any *detail method* where a micro-analytical technique, using paper chromatography has been fully described in relation to urinary 5-H.I.A.A.

The method is based on the simple expedient of cutting out the spot of the developed chromatogram which contains the 5-H.I.A.A., eluting it from the paper, and determining the amount of 5-H.I.A.A. in the eluate. It was *found that the* coloured product formed by staining the chromatogram with Ehrlich's reagent could be quantitatively eluted and its concentration determined colorimetrically. This was done by applying 5 µl. aliquots of a standard solution containing 2 µg. per 5 µl. 5-H.I.A.A. to Whatman no. 1 filter paper using an Aimer automatic ultra-micropipette (0·005 ml. capacity).

[8] Udenfriend, S., Titus, E. O., Weissbach, H. *J. biol. Chem.* 1955, 216, 499.

in an emergency with functions such as are defined in the Birmingham scheme.[4] The centre will provide a mobile team, such as is recommended for attendance at "major disasters".[5] The provision of a private telephone network with all its outposts should receive consideration.

Contact Between Outposts and Centre

No economy in medical man-power would be effected if it were proposed to staff each outpost or even such outposts as are at peripheral hospitals, with a casualty officer. The majority of minor injuries seen in casualty departments can be treated effectively by an experienced nurse, and indeed many of them are so treated at the present time. A clinic held by a doctor once a day for reassessment and supervision will make it unlikely that any important complication is missed. One doctor can thus control five or six outlying clinics. Although immediate medical attention to every trivial complaint or injury would not be given, the total medical cover would be increased, because more establishments treating such conditions would be supervised by the accident service. The medical cover, furthermore, would have some continuity of direction and policy, and, one hopes would be capable of making clinical advances.

Cases of acute superficial sepsis would be treated in their early stages at the outposts, but seen daily by the doctor "on circuit" who would decide when or if operation is indicated. He would be followed around by an ambulance which could pick up operation cases and take them to the casualty centre.

Injuries of a more serious nature such as extensive lacerations or obvious fractures would be referred to the centre. Major injuries would normally be taken there direct from the accident but occasional cases would have to be "staged" at outposts for first aid or even held at the peripheral hospital if unfit to travel farther. On such occasions the accident service should be prepared to send a doctor to the outpost, though every hospital, whether equipped to deal with accidents or not, should be prepared to hold those few cases which arrive unheralded and are obviously unfit to be transferred.

In this way the obviously trivial cases which constitute 90% of the casualty department's work, are filtered off. The doubtful acquire medical cover promptly, and transport is burdened only with those who need it.

Most important of all every outpost, whether situated at a peripheral hospital a clinic, or an industrial concern should be in constant touch with the casualty centre so that advice is always available and the chances of error in disposal are reduced to a minimum. Every doctor in the accident service, from consultant to junior house surgeon, should take turns in going 'on circuit, so that he is continually reminded of the problems in the catchment areas. No accident service can regard itself as complete if it sits in a department and waits for its cases to be brought to it.

A working knowledge of the local authority's services (police, ambulance, fire brigade) and of other organisations, such as pit rescue-teams, first aid societies, and N.H.S. reserve and Civil Defence Corps and an active attempt to make them aware of the proper disposal of accident cases will do much to send the injured straight from the incident to their right destination. There must also be a free exchange of nurses between outposts and the casualty centre, so that they are made aware of any advances in treatment. The attendance of voluntary or local authority employees concerned with the administration of first-aid should be encouraged. Industrial medical officers, having the care of a large number of workers, should be invited to bring their own first-aid posts into the scheme.

The Staff

The Nurses

An accident service designed on these lines will depend very much on the ability of its nurses, and there is no reason why this should not be so. A properly trained nurse is as skilled a dresser, and as accurate at skin suture, as a doctor, and she commands, or can command, as much respect. If a nurse can be trusted to bring us into the world, she can be trusted to sew up our cuts. In many areas there is no difficulty in recruiting for part-time duties, though there may be scarcity in resident nurses. Such part time nurses would appreciate the stimulus of close association with a medical centre, they would be proud to be members of its team, and they would welcome the opportunity to cooperate in the improvement of the medical services.

The Doctors

I believe that if one could offer young doctors membership of an efficiently organised and clinically satisfying section of the hospital system, with the prospect of teaching and support from more senior colleagues, there would be less difficulty in recruiting them for casualty posts. At present the casualty officer is very often left in isolation, and this should be remedied.

General practitioners should be brought into the service, not as stopgaps for a weak part of the hospital system but with benefit to themselves and to the service. Many of the proposed outposts could be supervised by them, as part-time members of the staff, and arrangements could be made for them to attend at the central hospital as well, so that they can keep themselves up to date in this type of work.

SUMMARY

1. The work of casualty departments in non-teaching hospitals is reviewed.

2. Many difficulties arise from lack of continuity in medical care, from shortage of medical staff and from the several unrelated duties that fall upon the casualty department.

These difficulties have only partially been overcome by enlisting the help of local practitioners by appointing senior casualty officers, and by making consultants "responsible on paper" for the work of the department.

As a result there are serious shortcomings at present, both in the standard of medical care and in administrative efficiency.

3. A plea is made for the establishment of comprehensive accident services and a scheme for such a service is outlined.

It would consist essentially of a central casualty department—housed in a hospital with facilities to treat all major accident cases either as outpatients or as inpatients—and of a number of outposts in close contact with the centre.

If the responsibility for receiving medical and surgical inpatients, for distributing outpatients to special departments, and for dealing with major accidents, were removed, the chief reasons for continuous medical cover in the smaller casualty departments would cease to exist.

Minor accident cases could be treated at the outposts by trained nurses under regular but not continuous supervision by doctors from the centre.

An efficient system would ensure the prompt transfer of all major cases to the central casualty department.

The requirements of such a centre are discussed, and particular stress is laid on the need for maintaining a general surgical rather than a purely orthopædic character.

A closely knit accident service would allow its medical and nursing members to keep abreast of advances in treatment, and it would provide opportunities for

The spots were dried after each application, and the chromatograms developed for three hours by the ascending technique in the following solvent system *n* butanol acetic acid water (4 1 5 v/v)[9] The chromatograms were then air dried and drawn through a solution of Ehrlich's reagent,[10] and the blue colour allowed to develop for eighteen hours The stained areas were then cut out as rectangles, allowing a suitable margin and choosing a size suitable to all concentrations One stained area of similar dimensions was taken from a position adjacent to one of the standard spots, and used as a solvent blank Each of the areas was then extracted with 3 1 ml of 50% acetone in 10% HCl at 30°C for twenty four hours and kept in the dark The extracted colour appears to be quite stable, even if exposed to light for several days

The absorption curve for the blue colour was established on a Unicam SP 600 spectrophotometer using 10 mm fused-glass cells, and by choosing a wave length of 610 mμ, a calibration curve was established which obeyed Beer-Lambert's law over a range of 0–20 μg 5 H I A A with an optical density of 0 223 for 20 μg The law was also obeyed by non chromatographed standard spots over the same range

BREAD

SIR,—I had hoped to see much correspondence concerning the proposed further reduction of the extraction-rate of wheat

Present day brown bread is not palatable I have heard complaints about this from many districts, and I myself have failed to procure any really good brown bread Even those firms which formerly provided delightful brown bread now produce a spongy sticky loaf Can it be due to a new method of baking?

Has the work of Sanderson Wells and of McCarrison so soon been forgotten? We of the older generation remember the beautiful nutty flavoured bread of our youth During the war I made delicious brown bread with yeast and stone-ground wholemeal flour, made from wheat grown on composted ground Several colleagues tell me that they have reverted to that practice, which produces a palatable loaf

London, W 1
AGNES SAVILL

SIR,—In the House of Lords debate on bread[11] the possible dangers of using chlorine dioxide as a flour improver were discussed, and the case against it failed However, no mention appears to have been made of its possible rôle in hypersensitive individuals Sheldon and Yorke[12] showed that flour treated with agene or chlorine dioxide was undoubtedly very harmful to their hypersensitive patient Their case resembles in many respects the syndrome of headache, insomnia, and depression following infections that I described recently[13] If further work shows that this syndrome is as common as I believe it is, and in some way is related to the "improving" of flour as I think it may be, then the present Government policy towards "improvers" should be reviewed In the meantime, I shall advise my patients to eat only untreated bread and flour if they wish to be on the safe side If such an attitude were to become a popular health fashion, "improvers" would soon disappear without any Government action

Hove Sussex
GUY DAYNES

SIR,—In the recent discussions on the composition of bread, insufficient attention seems to have been paid to certain aspects of the Food and Drugs Act

Section 1 makes it an offence for any person to abstract from food any substance so as to make it injurious to health The Act says nothing about the proportion of the population at risk, or about re balancing the diet to counteract the effect of processing—it is concerned with the right of "a person," in the singular, against another person Although most of the Act is concerned with the local authorities and their duties, this section can be used by any purchaser who complies with simple requirements on sampling No local authority, Ministry panel, or committee stands between the purchaser and the courts He must have the will, the money, and the evidence, but need wait upon nothing else The purchaser need not be the consumer

Hadley Wood
Barnet Hertfordshire
R MAXWELL SAVAGE

THYROTOXICOSIS

SIR,—It may help the busy clinician, in the "office" differential diagnosis of an anxiety state from slight thyrotoxicosis, to make the patient breathe deeply while the pulse is counted and note whether this produces a sinus arrhythmia

Sinus arrhythmia is mediated through vagal reflexes, which are suppressed by heightened sympathetic tone—at least at the level of cardiac innervation—in hyperthyroidism Though I have often noticed the appearance of sinus arrhythmia in patients as they become euthyroid after medical or surgical treatment of thyrotoxicosis, I have yet to meet a thyrotoxic patient who exhibits sinus arrhythmia I have met many anxious people who do

PARTHENOGENESIS IN HUMAN BEINGS

SIR,—In a recent lecture by Dr Helen Spurway,[1] the possibility of parthenogenesis occurring in human beings was mooted Moreover, some of the criteria by which such a birth might be recognised were put forward This led the *Sunday Pictorial* to inquire whether there were any mothers who genuinely believed that they had given birth to a parthenogenetic child It was stated that any such child would be a girl (Spurway later pointed out[2] that the possibility of parthenogenetic male offspring could not be ruled out, but they would be expected to be perhaps a hundred times as rare as parthenogenetic females, and in addition they would be defective)

Nineteen claimants presented themselves At this stage we were approached by the Editor of the paper with the request that we subject these claims to scientific investigation

In planning these investigations, two possible mechanisms of parthenogenesis were considered

(1) *Budding from somatic cells of mother*—In this case mother and child would resemble each other as much as monozygotic twins because the genotypes would be identical, not only for their blood groups, but also for all genes including those giving rise to the tissue antigens responsible for skin-graft compatibility

(2) *Autofertilisation*—In this case mother and child would not necessarily be alike, as the child might not have all the genes possessed by the mother although she could not have any additional genes A skin graft from the child would be expected to take on the mother, but one from the mother would not necessarily take on the child

Whichever of these mechanisms would be operative, the child could have no antigens which the mother did not possess

Of the nineteen pairs of mothers and daughters who presented themselves, eleven pairs were eliminated at the preliminary interview They were under the impression that a hymen which remained intact after conception had occurred, was what was meant by a "virgin birth"

further improvements It would help to solve problems which are at present created by a shortage of casualty staff, and ensure the more economical and more efficient care of patients both with trivial and with serious injuries

I should like to thank many casualty officers and nursing sisters in my own and other hospitals who have given time (which could ill be spared) to show me their departments, to discuss these problems, and to produce most of the information

Medicine and the Law

The Limits of Friendship

ON July 5, 1948, the Liverpool Radium Institute, formerly a voluntary cancer hospital conducting research as part of its work, was vested in the Minister of Health under the National Health Service Act, 1946 In September, 1948, people who before the vesting day had been associated with raising funds locally and in the North-west for the hospital, met to form a new unincorporated association, called the Friends of Liverpool Radium Institute The agenda and minutes of the foundation meeting stated that the object of the new body would be "to enlist support for research and scientific and medical developments as well as additional comforts and amenities for patients" Appeals were made as before, a series of leaflets were distributed to the public, and at the date of these proceedings the funds of the charity amounted to *£110,000*, *but in 1953* a divergence arose on the committee between those who thought that the object of the trust should be limited to activities connected with the institute itself and those who thought it extended to the wider use of the funds for cancer research generally or at least in the North west area To test the matter the committee resolved to make a payment of £800 to the University of Liverpool for a cancer research fellowship The trustees of the fund then asked the Court for a ruling, and on Jan 25, 1956, the Vice Chancellor of the County Palatine Court of Lancaster made an order which in effect declared that the funds could be donated to the wider purposes The institute appealed

Lord EVERSHED, the Master of the Rolls, said that though the formation of the new body and the framing of its object and rules had been rather informal, the words stating the object in the "foundation documents," the agenda and minutes of the inaugural meeting, made it clear that in their context the objects were limited to those directly concerned with the institute The minutes showed that the new body was to be a reconstitution of friends of the old hospital who would do for the hospital what the hospital as a nationalised institution could no longer do itself, the 'comforts and amenities for patients" must be limited to patients of the institute, and the words 'research development" did not mean development throughout the United Kingdom or the world, but were limited by the title Friends of the Institute," which was a cancer hospital "Research and development" therefore meant "cancer research and development" logically including the institute

His Lordship did not agree with the Vice Chancellor who had held that leaflets issued to the public appealing for funds showed that the primary purpose of the association was to collect money for cancer research generally, for anyone who gave attention to the leaflets would see that they were an *invitation by this body* formed in September, 1948, whose object was that for which it had been founded

The Court declared that the object was "for the purposes of cancer research and medical and scientific developments at, by, or under the direction of the Institute" The appeal should be allowed, and accordingly the resolution to devote £800 to the University of Liverpool for a cancer research fellowship was outside the scope of the powers of the trustees or the committee His Lordship expressed the hope that this decision would end the local dispute, for these funds were subscribed to use and not to hold, but if the differences continued, the Attorney-General for the *Duchy would no doubt* apply for a scheme

Lord Justice JENKINS and Lord Justice HODSON agreed

Shields v The University of Liverpool and Others—*Court of Appeal* Lord Evershed *M R* Jenkins and Hodson *L JJ* June 1 1956 Sir Lynn Ungoed Thomas *Q C*, *and Joseph Turner* (Walker & Co, Liverpool) Lionel Edwards Q C and W Lyon Blea (Alsop Stevens & Co, Liverpool) William Geddes (Bateson & Co), *Attorney General for the Duchy of Lancaster* (F Wilmer Holland, Q C), and Eric Griffith (Garnett, Tarbet Lindsay and Ellsworth for the Solicitor to the Duchy)

SOME HEART-MURMUR SIMILES

GEOFFREY BOURNE
M D Lond, F R C P
PHYSICIAN, ST BARTHOLOMEW'S HOSPITAL, LONDON

THE quality of some cardiac murmurs is a key to their type and origin Lewis years ago said that recognition of the presystolic murmur of mitral stenosis was analogous to the instant realisation that the bark heard was that of one's own dog This statement implied two things the difficulty of accurate description, and the necessity for listening so frequently to typical mitral presystolic murmurs that auscultatory diagnosis became automatic

I have for some time, in teaching, used certain similes in the description of murmurs A belief that such similes have been helpful is the stimulus for these few poetico clinical remarks

Diastolic murmurs, in rheumatic heart disease, may be caused by aortic regurgitation or by mitral stenosis and when differentiation between these seems difficult the quality of the murmur is often of great diagnostic value The diastolic aortic murmur, heard best in most cases down the left sternal border and to the apex, has the high pitched rushing and persistent quality of water escaping under pressure from a hose, over a weir, or from a leaky lock gate The diastolic murmur of mitral stenosis—not the presystolic—has the low pitched rumbling quality of a wooden wheelbarrow trundled over cobble stones Either of these murmurs may be loud and easily heard or distant and elusive, but the weir may be distant too, and the wheelbarrow in the next garden but one The quality of the sound is unchanged in both types of sound whether remote or near, *bucolic* or pathological

A less rural simile is applicable to the forcible harsh brief, systolic murmurs caused by the powerful ventricular expulsion of blood through a rigid and narrowed valve Examples of this are found in aortic stenosis pulmonary stenosis, and coarctation of the aorta The sound here suggests the deliberate forceful and short blasts of steam given off by the *Scottish express* starting from rest at King's Cross The sound may be heard from the other end of the station, or from farther off still, and may vary correspondingly in volume, but the character of *both steam blast and murmur* is very similar When this same type of murmur is due to coarctation of the aorta it is naturally much fainter than in the *other* two conditions

The so called "*machinery*" murmur heard in many cases of patent ductus arteriosus again suggests the Scottish express, but this time the sound is that heard by

The blood-groups of the remaining eight pairs were then examined with the following results

Mrs Alpha	A1	Rhesus phenotype c̄dec̄de
Daughter	A1	,, ,, c̄dec̄de
Mrs Beta	A1	,, ,, CCDee
Daughter	O	,, ,, CCDee
Mrs Gamma	O	,, ,, CCDee
Daughter	O	,, ,, CCDee
Mrs Delta	A	,, ,, Cc̄Dee
Daughter	A	,, ,, c̄dec̄de
Mrs Epsilon	A2	Rhesus positive to anti D
Daughter	A2B	,, ,, to anti D
Mrs Zeta	O	Rhesus phenotype c̄c̄DE
Daughter	O	,, ,, Cc̄Dee
Mrs Eta	O	,, ,, CCDee
Daughter	O	,, ,, Cc̄DE
Mrs Theta	O	Rhesus positive to anti D
Daughter	A1	,, ,, to anti D

Further blood-group studies were carried out on four of these pairs, and the results are shown in the accompanying table

—	M	N	S	P	Lu	Le^a	Le^b	K	Fy^a
Mrs Alpha	+	+	−	+ +	−	−	−	−	−
Daughter	+	+	−	+ + +	−	−	−	−	−
Mrs Beta	+	−	+	+ + +	−	−	−	−	+
Daughter	+	−	+	+	−	−	+	−	+
Mrs Gamma	+	+	−	−	−	+	−	+	−
Daughter	+	+	−	+	+	+	−	+	−
Mrs Delta	+	−	+	+ + +	−	−	−	−	+
Daughter	+	−	+	+ + +	−	−	−	+	−

Although the Betas could not be excluded on the blood group results (since the A1 antigen is known to tend to suppress Le^b) they were nevertheless eliminated on the colour of their eyes, the mother having blue eyes, and the daughter having dark brown eyes[3] One pair, Mrs Alpha and daughter, were selected for special tests as follows

(a) *Tasting of phenyl thiocarbamide* —Both were "tasters" and could taste this substance at the same threshold value of 2 54 mg per litre

(b) *Test for secretors* —Both mother and daughter did not secrete group A substance in the saliva, and identical titres against A2 cells were obtained after incubating treated saliva from both against a known anti A antiserum

(c) *Direct filter paper serum electrophoresis* —Mother and daughter gave identical patterns

Following these tests, skin grafting between mother and child was performed The graft from daughter to mother was shed in approximately four weeks, and that from mother to daughter remained apparently healthy for six weeks before showing signs of devascularisation It was then completely wiped off by means of damp cotton wool

It will be of interest to workers in related fields that, despite the complete identity of blood groups, there was still graft incompatibility This raises the problem of how far we can now accept earlier assumptions as to the behaviour of grafts in parthenogenetic pairs

In the case of the Alphas the probability of so good an agreement between mother and daughter, if the daughter had a father, is less than 1 in 100 It was 0114 on the blood groups The data on taste brings it below 01

It is clear that a very much higher degree of probability must be attached to a claim made by a mother who could not possibly have any pre knowledge of the results of these special investigations In certain cases this absence of pre knowledge has been taken by the courts to constitute proof of the rightness of a claim

No further tests were undertaken because it was considered that such evidence as might be forthcoming would not materially affect the final estimate of probability

The significance of the skin grafting operations is obscure Thus, while Spurway would expect that at least the graft from the child to mother would take, Folley[4] would apparently not be satisfied that such a result would be conclusive

In such a case as this, rigorous proof is impossible, but it remains that all the evidence obtained from serological and special tests is consistent with what would be expected in a case of parthenogenesis The absence of the pre knowledge factor, although not capable of precise statistical evaluation, adds greatly to the probability of such a claim being well founded Thus, this mother's claim must not only be considered seriously, but it must also be admitted that we have been unable to disprove it

It is desirable that all who undertake investigations of this sort should publish the results, for in the long run the evidence can only be fully assessed if negative and inconclusive as well as positive results are available for criticism

My thanks are due to Prof J B S Haldane, F R S, for permission to quote his statistical evaluation of the serological data, to Mr David Wynn Williams for undertaking the skin grafting investigation, to Dr Sidney Shaw, of Charing Cross Hospital, for carrying out the pathological investigation, to all these for permission to quote their results and opinions, and to Dr A E Mourant, director of the Blood Group Reference Laboratory of the Medical Research Council, for samples of the rare blood group sera I should also like to thank Dr Bernard Camber, of Charing Cross Hospital clinical research department, for his invaluable help and constant advice during this investigation

An investigation of this kind was made possible only by the publicity given by a mass circulation journal

London, W 8 S BALFOUR LYNN

VITAMIN K

SIR,—I have been interested in the effects of the two commonly used vitamin K analogues—acetomenaphthone and 'Synkavit'—for the past ten years The following notes on my experience in their use may be relevant to the current discussion in your columns of the dangers of overdosage with these substances, following the report (May 19) by Dr Bound and Dr Telford

For a number of years, I have used the above vitamin K analogues extensively for their apparent antibiotic effect,[5][6] resorting only occasionally and in special circumstances to the use of the popular and better known antibiotics I have consistently found the optimum oral dose of either to be 10 mg daily or, when supported by vitamin E and "vitamin P" ('Rutin'), 5 mg only, larger doses than these appear to have the reverse effect in many cases of infection and other conditions

In view of this limited range of dosage and also an apparent conditioned deficiency of nicotinic acid often accompanying their use, possibly analogous to that induced by the sulphonamides, I have come to the conclusion that the vitamin K analogues, given orally, may have a bacteriostatic effect on intestinal commensals, possibly by interfering competitively with their metabolism of natural vitamin K and thus lowering the synthesis of nicotinic acid as well as of bacterial toxins Significantly, I have found the foods reputedly most abundant in natural vitamin K[7] to be the most powerful in counteracting the observed favourable effects of oral vitamin K analogues

For these reasons and for fear of interference with the vitamin K metabolism of the host, I have studiously avoided the parenteral use of the analogues Moreover, it is possible that vitamin K may be involved in metabolic processes other than that of synthesis of prothrombin

The ease with which liver metabolism of natural vitamin K might well be disrupted by excessive parenteral dosage with synthetic analogues is suggested by the small dose (0 5-1 0 mg) of menaphthone (the naphthoquinone nuclear moiety of natural vitamin K[8]) quoted by Professor Capon and his colleagues (June 16) as adequate for the correction of hypoprothrombinæmia a passenger sitting in the train as it coasts downhill and with brakes off through the tunnels towards King's Cross

[8] *Ibid* p 798

The lub dub of the heart sounds corresponds to the coupled sounds made as the carriage rolls over the joints between successive pairs of rails, and the roar of the tunnel mimics the continuous murmur of the lesion, but the windows are shut and the sound is not too loud The roar seems to be intensified at each sound cycle, as the new pair of rails is reached, but this is an auditory fallacy In the heart lesion the systolic accentuation of the continuous murmur is real and not apparent The rhythm and the basic succession of sounds, in many cases of patent ductus recalls this picture, but here again the volume varies, in some cases being loud, in others moderate, and in yet others very distant

Another sound—a rarity—heard when an aortic valve cusp is severely ruptured, perforated, or perhaps even everted, as a result of syphilis or subacute bacterial endocarditis, is a diastolic croon This murmur closely mimics the coo of a near by and rather hoarse wood-pigeon which has been restricted to one rhythmic falling note instead of the usual three or four The murmur may be so loud as to be audible by the unassisted ear at a distance of several inches from the chest

A final simile, this time from the dance hall, is applicable to the friction rub of pericarditis

The drum beat of a dance-band playing a two step is a measurable fraction of time in advance of the shuffle of the dancers' feet upon a well chalked floor The double rub of the pericardial surfaces is similarly appreciably delayed behind the beat of the first and second heart sounds Sometimes the rhythm of the friction instead of being to and-fro is triple, and, to modify the metaphor, the dance becomes a waltz, not a two step, the third sound of the triplet being caused by auricular systole Once more it must be stressed that the quality and timing of the sounds are the important points The volume varies The shuffle of the dance may be quite loud, or if the ballroom door be shut may be heard only by close attention

CONSULTANTS' CONFERENCE

A CONFERENCE of over 300 consultants and specialists, organised by the central and regional consultants and specialists committees, was held in London on June 20 It was the first conference of its kind, and it was attended by members of the central committee and by representatives appointed by regional committees Mr A M A MOORE was in the chair After a private session in the morning, the conference heard an address by Sir RUSSELL BRAIN, chairman of the Joint Consultants Committee

THE DOCTOR'S POSITION TODAY

Sir Russell spoke of the present paradoxical situation in which the demand on hospital beds and outpatient departments was as great as ever, despite the striking medical progress of recent years which had enabled us to cure or control many diseases There was still more work for more doctors But, Sir Russell went on, the doctor could not get on with his job satisfactorily unless certain conditions were fulfilled He must be free to do his work without interference on matters for which he was personally responsible The task of the Government and all lay authorities was to create the conditions in which doctors could do their best work—" so far as possible, to give us the tools and leave us to get on with the job " Perhaps it was not generally realised, Sir Russell remarked, that this involved a new pattern of social organisation State services were usually hierarchical, and in medicine we had to combine a State organisation with individual freedom This was not an easy task, but Sir Russell believed we should succeed He thought there was a need to emphasise that the doctor occupied, and must continue to occupy, a unique place in the Health Service Medicine today was increasingly a matter of team work, but there must be a captain, and surely it was obvious that the more complex medicine became the more important it was that the responsibility for the patient should be in the hands of a single person—the consultant in hospital and the family doctor outside We were grateful, Sir Russell said, for the help which a growing army of technical experts gave to medicine, but it was the doctor in charge of the patient who must always decide how their services were to be used

When Parliament set up the National Health Service, it made itself responsible for the economic status of most doctors, and the present economic situation meant not only real hardship for those in the lower salary range but for all a deterioration in economic status relative to some other occupations, which, if we did nothing at all, might well be permanent This had not happened as the result of anyone's design but as the by-product of other people's actions and unchecked economic tendencies We faced here, Sir Russell declared, a challenge to the future of the profession But we must not let the difficulties of the times blind us to what had been achieved He believed that historians of the future would look back with astonishment at the establishment of the National Health Service between 1946 and 1956—a minor social revolution in which they would say, he hoped, that Britain, with characteristic wisdom, welcomed the new ways while conserving all that was best in the old

HOSPITAL MEDICAL STAFFING

At the afternoon session, Prof G I STRACHAN, chairman of the committee which reported last year on hospital medical staffing, told the conference that the plain fact was there were too many senior registrars Barring some such scheme as his committee had suggested, there were no alternatives but other employment or, to put it bluntly, unemployment The Joint Consultants Committee is now discussing this subject with the Ministry of Health, but, as the central committee's report puts it, " in view of the complexity of the problem early agreement is not to be expected "

Mr G WARING ROBINSON, chairman of the S H M O s' group executive committee, urged that there should be an expansion of the consultant establishment which should first absorb existing S H M O S Most S H M O s, he declared, were now doing consultant work A total of 10,000 consultants would not be too liberal an allowance for the population of this country, yet at present there were only about 6000 consultants and rather less than 3000 S H M O S Mr A STAVELEY GOUGH emphasised that Professor Strachan's committee had had no intention of worsening the present position of the S H M O , but he called this motion an irresponsible one It was nonsense to suppose that all S H M O S were doing consultant work When Mr Waring Robinson's motion was amended to read " absorb existing *suitable* S H M O S " it met with the conference's approval

After discussing other matters dealt with in the Strachan report, the conference agreed to the following motions

(1) " That this meeting is opposed to the introduction of any new career grade where the holders of such posts carry out work which should be carried out by consultants " (carried after a recount)

(2) " That in the event of the *reforming of the* structure of hospital medical staffing the grade immediately below consultant should be linked with the consultant grade and should be regarded as part of the senior medical staff "

It is surprising that the knowledge gained from study of the bacteriostatic action of sulphonamides, *p*-aminosalicylic acid, and other antibiotics has not been applied, long ere this, to the question of administration of vitamin-K analogues Incidentally, to swing the axe in another direction, this point is also relevant to Dr Schlesinger's allusion last week to over-prophylaxis against rickets The substance commonly used for this purpose is vitamin D_2 (calciferol), a synthetic analogue of natural vitamin D, and, in view of the above considerations relating to vitamin-K analogues, equally deserving of a more critical examination I described several years ago[6] some of its effects, short of idiopathic hypercalcæmia

Merioneth
North Wales

D Marcus Evans

PARAPLEGIA FOLLOWING SPINAL ANÆSTHESIA

Sir,—I hope that Sir Francis Walshe's verbal pyrotechnics do not blind your readers to the fact that the only opinion I have expressed on spinal analgesia (under the above heading) is that it is dangerous to store ampoules of the local anæsthetic solutions in antiseptics

Oxford

R Macintosh

Sir,—Sir Robert Macintosh (June 16) replies to my letter of June 9 by questioning the training, skill, and experience of the anæsthetists to whom I referred For his information I would point out that they were specialist or graded anæsthetists R A M C, I M S, or I A M C Ashley Daley in the *Medical History of the Second World War, Surgery* (p 221) details the training to which they were subjected

Sir Robert's reference to the unknown unaccounted dead of ill-administered general anæsthesia is apt. Death, however, is recognised as a hazard of general anæsthesia Patients about to be anæsthetised are conditioned to the possibility that the end-result may be death I doubt, however, whether any patient would opt for spinal anæsthesia if it was explained to him that the horror of paraplegia was a possible fate in store

I venture to say, Sir, that, in these days of efficient relaxants, there is no place in our armamentarium for spinal anæsthesia Before many years have passed this will come to be accepted by all surgeons and anæsthetists It is time the leaders of our profession abandoned the practice and teaching of this outmoded technique

London S W 3

L H Lerman

Sir,—This problem seems to have two parts

The first concerns the sequence of events which brings about disaster, and especially the possible rôle of phenol We know that phenol when placed intrathecally will generally have a destructive effect upon nerves but we also know that it may not always do so (Haxton, June 23, Steel, June 9) At the moment we can only say that, where phenol is involved, it may be, but is *not* necessarily, the cause

The second concerns the justification for the continued use of spinal anæsthesia

Dr Lerman proposes the all too easy solution of abandoning it With all respect I disagree with this We cannot be sure that there will never be a combination of circumstances which will make spinal anæsthesia the method of choice, and it would be unwise to restrict the doctor's freedom to choose what will best serve the interests of his patients We can no more solve this problem as Dr Lerman suggests than we can solve that of inhaled vomit in operative obstetrics by issuing an embargo upon general anæsthesia As Professor Macintosh has pointed out, the latter is by no means free from risks or complications nor is any form of anæsthesia thus blessed We should not forget that anæsthetic hazards, regional and general, are essentially secondary, since they spring from the primary hazard that the patient has already suffered—that of becoming a person requiring operative treatment Without running the gauntlet of these secondary hazards, it may be impossible to overcome the primary misadventure It is our duty on some occasions to undertake these remote risks in the hope that the patient may thereby benefit

I submit that spinal anæsthesia is, in some circumstances, a wholly justifiable procedure

London S W 15

G C Steel

Sir,—For some years I have been impressed by the possibility of neurological complications following spinal anæsthesia, and I now rarely employ the technique Nevertheless, in spite of the condemnation of several writers, I am convinced that the method will continue to be used because, in some circumstances, it can rationally be judged the safest, even though the occurrence of neurological complications be admitted If this be so, then the important matter is to try to make the procedure as safe as we can To this end no doubt research is needed, as has been suggested, but so is reasonable thinking

Sir Francis Walshe (June 23) regards the injection of "an anæsthetic substance" as the salient common factor in the ætiology of these complications and charges an unnamed fellow medical man with being "completely simple" in ignoring this proposition It seems to me that the problem is by no means so straightforward, and I would like information on the following questions

1 Can we assert with assurance that "neurological complications" never follow upon spinal puncture for diagnostic purposes, without the injection of anything? It seems to be difficult to be sure of this, for such a puncture is usually done in the presence of real or suspected disease of the nervous system and the rare occurrence of a complication could be confused with the developing effects of disease

2 If, however, we assume, as Mr Haxton (June 23) carefully puts it, that "the risk is inherent in the injection" then is the deleterious factor (*a*) some physical effect of the injection of fluid, (*b*) the anæsthetic solution, remembering that these are chemically various and may very often be injected without damage, or (*c*) an accidental *contaminating* substance of which an infective agent, a skin disinfectant, or the carbolic solution provide examples?

3 Is it likely that there is a single causative mechanism or are there probably several? In general, the diagnosis of the location and extent of the lesion of the nervous system *does not necessarily* determine its nature, much less its cause

The research, both experimental and by study of clinical experience, needed to solve this problem will be complicated and lengthy Meanwhile we must concentrate on the most likely dangers, and wisely to select these requires calm thinking and ordinary courtesy toward varying viewpoints

Department of Anæsthetics,
The Medical School
Newcastle upon Tyne 1

E A Pask.

EPHEDRINE POISONING

Sir,—In the following case of chronic ephedrine poisoning the patient had taken large doses of this drug for a long time

On Jan. 6 this year a 49-year-old man was admitted to a surgical ward with a diagnosis of Graves's disease He had had symptoms referred to the nose and throat since the age of 20, and of asthma since the age of 24 He had had pneumonia five times, and had twice been operated on for adenoids In 1947 he had been tested with various kinds of pollen and grain, and had been vaccinated without effect The patient had for some years been taking ephedrine and, in severe attacks adrenaline In the past five years his asthma had increased in severity He had spontaneously increased the dosage of ephedrine until, in the past two years, he had been taking 1–1 5 g of the drug daily This dosage had caused palpitations, which had become more pronounced He had become nervous and restless and his hands trembled He had attacks of hot flushing, especially at night, and he sweated profusely He had lost 8 kg in weight despite a large appetite He felt as if his eyes were being pressed out of their sockets, and had a constant sense of tightness round his throat

(3) 'That in any hospital restaffing the number of senior assistants should be strictly limited in order not to exploit the grade'

(4) 'That, in view of the disparity in consultant establishments in various hospitals, a minimal standard of consultant staffing in relation to the number of hospital beds should be recommended'

MEDICAL ADVISORY MACHINERY

Dr A **ROWLAND HILL**, deputy chairman of the central committee, said the committee had consistently pursued its policy of seeking to improve the medical advisory machinery at all levels in the service But the position was not satisfactory and he feared the domination of lay advice, hospitals, it seemed, had an attraction for those with a love of power One proposal aimed at improving matters was put before the conference the suggestion that there should be a medical advisory committee to each regional hospital board was approved The majority of members of this committee should be elected by the consultants and SHMOs in the region

MILEAGE ALLOWANCES

After considering the adequacy of the present ca mileage allowances, the central committee decided th there was not a sufficiently strong case for seeking an improvement in the rates But the conference di agreed and held that "in view of the increased rat of depreciation in car values and the need on ground of reliability for consultants *to maintain reasonabl* modern cars," the time had come for an increase in th mileage allowance

POWER OF THE CONFERENCE

The conference was asked to say that resolution passed by it and future consultants' conferences shoul be binding on the Central Consultants and Specialist Committee Mr T **HOLMES SELLORS**, chairman of th committee, said the original idea was that the conferenc should be advisory and not policy making, and he wa reluctant to see that principle changed at present Th conference voted in favour of remaining an adviser

CONSULTANT AND OTHER SPECIALIST STAFF IN HOSPITALS

THE Ministry of Health and the Department of Health for Scotland last year issued figures for consultant and other specialist staff in National Health Service hospitals up to the end of June, 1954[1] These Departments have now carried the figures forward a further year

In table I (not reproduced here) they show the age-distribution of consultants and senior hospital medical officers in each specialty and the number of paid session undertaken by those in each specialty for each year o birth

Table II shows the number of consultants in each o the specialties year by year from 1949 The corresponding figures *for SHMOs are not available*

Table III shows the number of senior registrars in each specialty on June 30, 1955, at the various levels o training

TABLE II—NUMBER OF CONSULTANTS IN EACH SPECIALTY AT VARIOUS DATES SINCE DEC 31, 1949 (GREAT BRITAIN)

When examined in the medical outpatient department on Jan 13, he was nervous and restless, his hands trembled, skin moist, warm, and shiny, eyes slightly protruding, pulse rate 100 per minute, blood pressure 180/100 mm Hg The right lobe of the thyroid gland was slightly enlarged There were clinical signs of emphysema Total serum-cholesterol 228 mg per 100 ml Measurement of radioactive iodine (^{131}I) uptake showed 45 9% uptake in twenty four hours Basal metabolic rate 129%

After treatment with ephedrine was stopped all signs of hyperthyroidism disappeared

No similar case has, to my knowledge, been recorded This case may be of some interest in elucidating the ætiology of Graves's disease

Rikshospitalet, Oslo, Norway ANTON E ODEGAARD

MEDICAL CARE OF THE AGED

SIR,—It was of interest to learn, from your review of June 2, that Dr Homburger's book was illustrated by that celebrated Hibernian artist Raoul "Duffy" We can now look forward to medical illustrations by his equally famous Celtic colleague MacTisse!

Department of Medicine,
State University of New York MILTON PLOTZ

THE HEBERDEN SOCIETY

SIR,—In your report (June 16) of the recent meeting of the Heberden Society we are quoted as having said that an antibody prepared by immunisation with synovial tissue reacted with reticulin, whereas an antibody to renal glomeruli did not In fact we reported that antibody to glomeruli had been found to react with two groups of tissue elements—basement membranes and material present in the media of vessels forming one group, and reticulin the second Antibody to synovial tissue, on the other hand, reacted only with the second

INFANTILE PYLORIC STENOSIS

SIR,—In your very interesting editorial of May 19, the rôle of the ethnographic factor in the ætiology of this disease has been omitted

Wallgren[1] cited Eckhaus from Turkey, showing that hypertrophic pyloric stenosis was rare in that country Field[2] reported likewise about Malaya It is believed that this disease is rare among Negroes[3] In 1953 we made a survey in Israel[4] and found that the incidence of infantile pyloric stenosis in the Jewish population was much lower than that reported from Sweden[1] or England[5]

Further surveys of the incidence of this disease in the whole population of a given area, performed in different parts of the world and in areas with a population of mixed extraction, could help to clarify this challenging part of the question

MEMORIAL TO SIR JAMES SPENCE

SIR,—The friends and colleagues of Professor Sir James Spence in the University of Durham and the Teaching Hospital of Newcastle upon Tyne are anxious to commemorate his name and perpetuate his memory in ways which he himself would have appreciated To this end it has been decided to appeal for funds for the following purposes

To award a medal for outstanding contributions to pædiatric knowledge—The award would be made from time to time by the British Pædiatric Association, usually, but not exclusively, to persons working in the United Kingdom or in any country of the Commonwealth who have made outstanding contributions to the advancement or clarification of pædiatric knowledge within the fields of clinical and social pædiatrics, clinical science, epidemiology, and family practice

To establish an annual prize in pædiatrics for the students of this medical school—This would consist of a sum of money and a volume of James Spence's collected writings to be awarded to the student submitting the best essay on any pædiatric subject which has excited his interest and led him to personal inquiry during his clinical training

To provide a sculptured portrait head to be cast in bronze—This would be placed eventually in the new Children's Hospital which we trust will be erected within the precincts of the Royal Victoria Infirmary

We feel that these proposals will prolong his influence in ways which will commend themselves to his many friends We would add that the university is being invited to rename the chair he held with such distinction "The James Spence Chair of Child Health"

Donations will be received by Dr A W Sanderson, House Governor and Secretary, the Royal Victoria Infirmary, Newcastle upon Tyne

URSULA RIDLEY
Chairman of the Babies Hospital House Committee
C I C BOSANQUET
Rector of King's College
R B GREEN
Dean of Medicine
R MUCKLE
Chairman of the Board of Governors
S D M COURT
Newcastle upon Tyne Professor of Child Health

The Editor of the *Medical Directory* writes "The accuracy of the directory depends on the return of the annual schedule, which has recently been posted to members of the medical profession Should the schedule have been mislaid I will gladly forward a duplicate upon request The full name and year of qualification of the doctor should be sent for identification" The directory is published by Messrs J & A Churchill, Ltd, 104, Gloucester Place, London, W 1

Parliament

QUESTION TIME

Thermonuclear Weapons

Mr ROY MASON asked the Secretary of State for Foreign Affairs whether, in view of the Medical Research Council's report on the hazards to man of nuclear and allied radiations and its findings regarding the danger of strontium 90, he would now seek international agreement with the major Powers concerned at least strictly to control all future atomic and thermonuclear tests

Mr A D DODDS PARKER replied, The Government are prepared to discuss methods of regulating and limiting test explosions which take account of their position and that of other Powers and will seek every opportunity to put this policy into effect The Government have already put forward proposals which will, no doubt, be considered by the Disarmament Commission next month

Mr KENNETH YOUNGER Would the Foreign Secretary agree that the white paper and the corresponding medical reports of a similar nature which have been published in the United States are of a rather alarming nature, indicating, in particular, that scientists have very little idea what the medical effects are likely to be? There is a great lack of precise knowledge Does not that indicate that some action rather more urgent than that contained in the Anglo French proposals is now required? Mr SELWYN LLOYD One must form an individual judgment as to these reports I should have thought that, on the whole, the reports were rather reassuring

Fall-out of Radioactive Particles

Mr MASON asked the Lord Privy Seal what research was being conducted into the possibilities of controlling radioactive fall out over the United Kingdom—Mr R A BUTLER

displayed laterally A pack is then inserted, gowns and gloves are changed, and the patient is placed in the Trendelenburg position Node dissection and dislocation of ureters is performed as usual, but division of the parametrium is then greatly facilitated since the operator can pass a finger from rectum to bladder beneath the specimen to be removed and thus display more clearly the uterine ligaments

No claim to originality is made for this procedure, which is the logical result of the solitary operator attempting to apply the excellent principles laid down by Mr Howkins It has worked well enough in 5 recent cases and, somewhat modified, in a similar number of patients with carcinoma of the uterine corpus It certainly allows a clear decision to be made at the beginning of the operation regarding the amount of vagina to be removed, it gives better access for the control of bleeding points deep in the pelvis, and it makes excision of the parametrial tissue safer and more radical for the less experienced surgeon

Birmingham W G MILLS

CLINICAL PATHOLOGY

SIR,—One may read with enthusiasm the report, printed in your issue of Dec 31, of the presidential address by Dr Allott to the Association of Clinical Pathologists The vision, balance, and broadmindedness shown in his description of the future laboratory service, particularly with regard to chemical pathology, would be near perfect but for the unfortunate fact that there is not the slightest real indication that administrative change is in the direction to which Dr Allott points

He speaks of necessary expansion Before any would-be trainee or aspiring registrar in chemical pathology binds his future to this specialty he should note that the trend during the past few years has been, not towards expansion, but towards contraction Since 1948 there have been fewer than 18 posts, including "turnover posts," in chemical pathology advertised, and of these, at least a third have either been changed subsequent to advertisement to non-medical biochemist, or, in a few cases, withdrawn altogether and no appointment made

The would-be aspirant in chemical pathology would therefore be well advised to note that, as things stand, his chances of a hospital post are small—indeed almost negligible Furthermore, human nature being what it is, he will seldom be more than S H M O—however good his work is admitted to be

S H M O (chemical pathology)

ECZEMA VACCINATUM

SIR,—Dr de Salles Gomes and his colleagues, describing in your issue of Dec 17 a case of eczema vaccinatum, mention that they have not been able to find any published report of such strict localisation as was found in this case—i e, limitation of the lesions to the eczematous patches My experience and that, I believe, of other workers in this country is that such localisation is not so much the exception as the rule Of ten cases reported by Sommerville, Dick, and myself[1] the eruption was limited to the eczematous areas in eight, while in the ninth it affected an area of acne and in the tenth an abrasion

The Brazilian workers favour the hæmatogenous spread of the vaccinial infection, with entry through the respiratory tract, whereas in the article quoted we give reasons in support of direct inoculation of the virus A point of significance is the frequent appearance of enlarged tender glands at the sites draining the infected area, such as is mentioned in the case-report from Brazil "a hard painful lymph-gland in each crural region" Surely this indicates infection travelling inwards and not outwards

Infectious Diseases Hospital,
Paisley WILLIAM NAPIER.

INGUINAL HERNIORRHAPHY

SIR,—May I supplement Mr Doran's article of Dec 24?

As an alternative to suturing the conjoined tendon to the upper edge of Poupart's ligament, I reflect an elliptical flap of the anterior rectus sheath with its base on the outer edge of the rectus sheath, and suture the free turned-down edge of this to the upper edge of Poupart's ligament with interrupted nylon sutures I have used this method on adults for twenty years and have been satisfied with it An added refinement, which I have not tried, would be to suture the conjoined tendon to Poupart's ligament, leaving the ends of the interrupted nylon sutures long, reflect a flap of rectus as already described, and pass the long suture ends through the free edge of the turned-down flap

Longtown Cumberland ROBERT RUTHERFORD

MODIFIED QUECKENSTEDT TEST

SIR,—It has long been recognised that occlusion of the internal jugular vein by manual compression slows absorption of cerebrospinal fluid and so causes the pressure in the ventricles and spinal canal to rise Such manual occlusion is applied *in the Queckenstedt test* Raising the venous pressure by crying or coughing has the same effect

Compression of the internal jugular vein is commonly not done effectively by nurses, and it causes considerable discomfort to the conscious patient An efficacious alternative is to ask the patient to inspire and then forcibly expire against the closed glottis In all cases in which I have used this method at lumbar puncture, and compared the effect with that of compression of the internal jugular vein, the rise and fall in cerebrospinal-fluid pressure has been identical This method is not only more comfortable for the patient, but does not require the cooperation of an assistant

Nelson New Zealand C H BELTON

"BURNS" IN THE ABSENCE OF FIRE

SIR,—Last year Sir Harold Whittingham and his colleagues described the injuries in the Comet aircraft disasters[1] In the Elba Comet disaster, changes with the appearance of burns were found in the skin but there was no singeing or burning of the clothes or hair Several possible causes were discussed, and it was concluded that the most likely one was fire starting after the bodies had fallen into an area of sea covered by a kerosene film and that scalding occurred Fryer has since declared that the skin changes "were found to be due to" this cause[2] This touch of finality is perhaps not justified In the original article it was stated that this type of "burning" was not familiar to forensic pathologists It is worth recalling, therefore, the Senghenydd coal-mine explosion in South Wales in 1913, which was the worst disaster in British mining

Of 458 men working in the western side of the mine, 440 were killed and 18 were rescued and survived Some of the survivors showed areas of what appeared to be burning, but they came from a part of the mine where there had been no fire In the Elba Comet disaster, 14 of the 15 bodies showed skin damage simulating burns, and in 13 the injury was on the back or buttocks In the coal-mine disaster, of the 18 men rescued, skin lesions resembling burns were found in 9, and the buttocks likewise were the commonest sites, 5 were affected on the right side and 3 on the left, and in 1 the buttocks escaped In several of the men there were also lesions over bony prominences, such as the ischium The mine survivors were suffering from carbon-monoxide poisoning, and Davies[3] concluded that it was the main cause of the skin changes, and that local pressure from sitting or reclining was a contributory cause In the Comet cases some of the affected areas were traversed by bands of apparently undamaged skin, suggesting that some local condition of the skin surface influenced the development of the lesions

[1] Armstrong J A, Fryer, D I, Stewart, W K Whittingham H E *Lancet* 1955, i 1135
[2] Fryer D I See *J clin Path* 1955 8 348.
[3] Davies I J *Brit med J* 1914, ii 57

Other instances of burn-like lesions with carbon-monoxide poisoning have been recorded, and it may well be that other forms of anoxia could have similar effects Perhaps some of the "burns" in babies with asphyxia are due to anoxia and not to hot-water bottles

In writing this letter I do not wish to suggest that the Comet "burns" were caused in the same way as those in the mine but rather to draw attention to mysterious "burns" in circumstances where it is known that there has been no fire

Medicine and the Law

Death of Patient with Artificial Pneumothorax

A WOMAN, aged 46, with a long history of pulmonary tuberculosis died soon after an attempt to refill an artificial pneumothorax No air-space had been found with short refill needles A longer one was tried without success, and the operation was then abandoned Soon afterwards the patient became unconscious, and she died about an hour later Necropsy showed that the intrathoracic structures had been distorted by the long-continued pulmonary disease and that the aorta had been punctured by a needle A verdict of death by misadventure was recorded [1]

Osteopath Criticised at Inquest

The possibility of a verdict of manslaughter was mentioned at an inquest into the death of a young man following treatment by an osteopath [2]

The dead man was Frank Marsden, a 24 year old bank clerk, of Ossett, near Huddersfield Marsden suffered from curvature of the spine and pains in the feet which he attributed to rheumatism, and he consulted Mr Leonard Redfearn Carter, described as an osteopath and naturopath After examining him, Carter gave a hopeful report and prescribed dietary treatment Marsden had kept rigidly to these diets over a period of fifteen months to the day of his death

Dr W L Rose, who conducted a post mortem examination, said that the cause of death was malnutrition due to inadequate food intake "In my opinion," he said, "to keep this boy on these diets for a long period was absolutely criminal" Giving evidence, Carter said that he took up his present practice nearly thirty years ago after passing examinations He was firmly of the opinion that the diets he had prescribed would cure the rheumatism, but he admitted that they supplied only 1500 calories a day

The coroner told the jury that, if they thought that Carter had been so negligent as to cause death in a criminal way, that would be a question of manslaughter, but the evidence did not seem as strong as that The jury returned a verdict of death by misadventure

A Patient 30 Miles Away

Worcestershire Executive Council has decided that it was unreasonable for a Birmingham doctor to include in his list a patient living at Pershore,[3] on the ground that the doctor could not, from 30 miles away, fully comply with the terms of service It was stated on behalf of the doctor that he expected the patient to return to Birmingham, where he had formerly lived, and that he had in fact treated the patient in Pershore The chairman of the council is reported to have said "We can't prove the doctor could not render service," but the council decided to advise the patient to attend a local doctor

Obituary

WILLIAM GILCHRIST PATTERSON

M D Edin, F R C P, D P H

Dr Patterson, who died on Jan 5 at the age of 55, was the first senior administrative medical officer appointed under the National Health Service, and was often the spokesman for his colleagues. His previous work as medical officer of health for Surrey had given him unusual knowledge of the planning and management of hospitals, and in his eight years with the Newcastle Regional Hospital Board he won respect and admiration by an administrative ability based on intelligence, understanding, and courage

He was the second of three brilliant sons of George Patterson, who in his later years was headmaster of Whitburn School in West Lothian, and much of his youth was spent in the Lothians countryside At George Heriot's School in Edinburgh, where he was dux and played for the first fifteen, a distinguished future was forecast for him, and, after serving for a short time in a combatant regiment, he continued to win honours at Edinburgh University, including the Ettles scholarship for the best student of his year He qualified in 1924 with first-class honours, held various house-appointments in general hospitals and mental hospitals, and then had a period in general practice before concentrating upon a career in public health

Patterson's first public-health post was that of medical officer of health for the Chertsey combined district, and this was followed by appointment as M O H for the county borough of Barnsley From Barnsley he returned to Surrey as deputy to Dr James Ferguson This was the time when some of the major local authorities were going rapidly ahead with new hospital services, and Patterson, whose heart was in this from the first, took a big share in the Surrey schemes by which many hospitals were upgraded and a new one was built at St Helier The Surrey system differed from the neighbouring one in Middlesex in that it gave more scope for part time consultants though Patterson thought that hospitals gained by having a medical superintendent, who should be one of the senior clinicians, he held that, in appointing consultants, they should secure the best men they could get, and not limit the field by asking whole-time service Under Ferguson's inspiration the Surrey policy was one that made a particular effort to preserve, in the municipal hospital, part of the pattern of the voluntary hospital, and association between these two kinds of hospital was closer in Surrey than it generally was elsewhere

Owing to the war, and the additional strains it imposed on the county organisation, Ferguson's retirement was deferred and Patterson did not succeed him as M O H till 1946, when the county was already about to lose its hospitals altogether No doubt it was because of the closing of this chapter in hospital administration that he went in 1947 to Newcastle upon Tyne to help in opening another

Newcastle was certainly fortunate in his being available and wishing to move to the North The region was not an easy one to organise some of the municipal hospital services had been developed exceedingly well, but bed provision and standards in many areas were lagging a long way behind Long before the appointed day Patterson had made a detailed tour of all the hospitals in the board's area and had met most of the senior staffs Once he had made his surveys he could see things remarkably clearly, and as a result the board's programme for development was skilfully and fairly laid down in accordance with his advice If, through his strength and knowledge, he was a somewhat dominating personality, the relations between the board and its officers were as good as anywhere else in the country Moreover, he soon made a name and created a respect for himself in the region among members of all the various health services He was intensely interested alike in the general practitioners, in the consultants and in the medical nursing, and hospital staffs, and he never lost his sincere interest in the public-health service Nothing pleased him more than when he, a senior

When involved in these decisions ?—Miss HORNSBY SMITH Jan ' Thirty projects at a total estimated cost of £340,000

skin EDITH SUMMERSKILL In view of the fact that the minister showed sympathy with the Guillebaud report, the chief recommendation of which was to provide capital expenditure for hospitals, can the hon Lady say why this attitude is adopted at this stage ?—Miss HORNSBY SMITH The Guillebaud Committee repeatedly laid down the principle that, whilst many items might be desirable, they would have to conform to the general economic circumstances of the country, and that is the principle we are following here

Social-security Reciprocity with Sweden

Replying to a question, Mr J A BOYD CARPENTER, Minister of Pensions and National Insurance, said that an agreement had been reached with Sweden on reciprocity in social security Besides covering the benefits provided by the schemes of National Insurance, Industrial Injuries Insurance, and National Assistance in this country and the corresponding benefits in Sweden, the agreement would enable British families to draw Swedish family allowances as soon as they became civilly registered in Sweden Legislation at present before the House would enable this country to make a corresponding concession in our scheme of family allowances An important feature of this agreement was that British nationals who visited Sweden would be able to make full use of the Swedish health services Agreements with other European countries had enabled British nationals to use the health services of those countries if they were working there, but Sweden was the first country outside the Commonwealth to offer full reciprocity with the United Kingdom by making its health services available for all British nationals, including tourists The agreement required ratification, and the date of its operation would be announced later

Protection of Children

Replying to a question, Major GWILYM LLOYD GEORGE, Home Secretary, said that the terms of reference of the committee which he proposed to appoint[1] would enable it to study the problem of preventing or forestalling the suffering of children through neglect in their own homes and to make recommendations for any change in the law Meanwhile he was arranging, in consultation with the Ministers of Health and Education, for a survey of the existing arrangements for coordination, and as a first step local authorities would be asked for up to date particulars of the arrangements operating in each area

Mr G S DE FREITAS Is it not right that we should take account of the recent findings of the British Medical Association and the magistrates that family welfare work has been hindered by the number of people and organisations concerned ?—Major LLOYD GEORGE Coordination is the better way to deal with this Many local authorities have had coordinating committees, which have done good work I entirely agree that coordination is most important, and I hope that the work of local authorities will be coordinated

Replying to a further question, Major LLOYD GEORGE said that, as at present advised, he would not feel justified in proposing in the case of this offence the quite exceptional step of raising above six months the term of imprisonment which magistrates had power to impose From long experience he knew that the powers were sufficient but often were not utilised

Health Education and the Effects of Alcohol

Replying to questions, Mr DENNIS VOSPER, parliamentary secretary to the Ministry of Education, said that the Ministry s handbook of suggestions on health education designed for teachers and parents contained a passage on alcohol, and he had no doubt that most pupils received advice on this matter The Minister of Education agreed with the Royal Commission that Teachers should be left free to handle it as they thought best The handbook was about to be reissued, and this would contain a new passage referring to alcohol

Obituary

ALFRED HOPE GOSSE

T D , M A , M D Camb , F R C P

Dr Hope Gosse, consulting physician to St Mary s Hospital and to the Brompton Hospital, died on June 23 He was 73 years of age and was in his usual health until a fortnight before He had lately remarked on his good fortune in being granted a bonus of three years over the allotted span of three score years and ten

Alfred Hope Gosse received his early education in South Australia, but his later training was at Caius College Cambridge, where he took his B A in 1907 He spent the clinical years of his medical course at St Mary's Hospital, which he entered as a student in 1908 and from which he qualified in 1910 After filling the post of house-physician he became medical registrar in 1911 When war broke out in 1914 he spent a year or two as registrar to the 3rd London General Hospital (Territorial), but in 1916 he volunteered to go to Mesopotamia with 40 B G H He was soon appointed officer commanding the officers' hospital at Beit Naama, where he ran a very efficient unit He was thrice mentioned in despatches and was promoted brevet-major

On his return home in 1919 he was elected physician to outpatients at St Mary's Hospital He had done some work with Sir James Mackenzie, and from the start he decided to specialise in diseases of the heart and lungs This was furthered by his election to the staffs of the Brompton Hospital and of the King Edward VII Sanatorium, Midhurst He was elected F R C P in 1923 Between the two world wars Gosse carried on a large consulting practice, though he never let it interfere with the faithful discharge of his hospital duties He was a careful and accurate clinician, and a very acceptable teacher Large numbers of students used to attend his clinic at the Brompton Hospital, where his clear and dogmatic teaching was much appreciated During the late war he spent a large part of his time at St Mary s Hospital, doing a great amount of teaching and encouraging the students by his example and advice Though working in the Emergency Medical Service he refused to take any remuneration In 1917 he retired from active hospital work, but he continued in private practice till three years ago

In his prime Gosse was one of the leading cardiologists in this country His care and conscientiousness inspired confidence in his judgment, his kindness and sympathy gave the patients hope His long connection with the Medical Sickness Society gave him an unrivalled knowledge of the incidence of disease among doctors, and the few papers he wrote on that subject are of exceptional value

In 1933 he was made president of the Harveian Society but he took an even greater interest in the Medical Society of London, of which he was president in 1912 and had acted as honorary treasurer for the last 22 years A good mixer, he was an oarsman and tennis player in his youth and in later life he enjoyed watching a match at Lord's or spending a day at Goodwood

One of his friends has written " in a long life I have never met a more fair-minded, entirely upright man " Another, T C H , speaks of his clear purpose and integrity

' Few physicians in London can have had a greater number of true friends than he, and his complete honesty and sincerity made all who knew him trust him to the full He was always on the look out to help others and always careful to do so unobtrusively Kindness and hospitality were part of his very nature and there are many of his juniors who owe

him much both in practical ways and for his interest in their welfare and his common sense advice and guidance Gosse had a direct and clear approach to problems His way of brushing aside non-essentials often seemed at first too simple and blunt, but in the end often proved to be the best He had despite his forthright opinions and firm way of making decisions a sensitive and even diffident nature, and he could be easily hurt and distressed if he thought he had been unfair to others or had been treated with discourtesy or dishonesty He was incapable of deception himself and hated it in others His modesty made him a man who did not like outward show and he could never tolerate hypocrisy. He was afraid of giving others trouble of any sort, but would go to any length to do things for them As a physician he had a clear idea of what he meant to achieve, and he did not allow too many doubts to weaken his conclusions, so that he was able to give his opinion with a clearness and force that was greatly appreciated both by patients and doctors His teaching was direct and his handling of patients set an example of gentleness and humour which his students remember with gratitude"

In the words of Sir Zachary Cope, to whom we are indebted for much of this memoir, he was "a most faithful absolutely reliable friend, a man who scarcely ever spoke ill of anyone, a man to whom one could trust one's last penny and one's reputation There are many who will feel that some virtue has gone out of them, now that Gosse has departed."

IAN MURRAY BURDON

M.B Glasg, F.R C S.E

Mr Ian Burdon, visiting surgeon to the Victoria Infirmary, Glasgow, died in hospital on June 16 He was in his 56th year.

He received his early education at the Glasgow High School and graduated in medicine at Glasgow University in 1923 After house-appointments at the Victoria and Western Infirmaries he returned in 1926 to the Victoria Infirmary, where he remained, becoming surgeon in charge of wards, in 1947

A colleague writes

During his earlier years Ian Burdon worked with Mr Robert Carslaw, the late Mr Robert Tennent, and the late Mr Norman Davidson, all accomplished general surgeons, and during his thirty years' association with the Victoria Infirmary he similarly kept his surgical interests wide, though the field of biliary surgery claimed his special attention and study Before the inauguration of the health service, he did a great deal of emergency surgery in the smaller hospitals in the West of Scotland such as Dunoon and Rothesay, while in addition he was surgeon for a number of years to the Glasgow Homœopathic Hospital

His surgery was characterised by great facility, for he had the artistic temperament and was a superb craftsman. He was not so much an innovator as an improver and refiner of existing methods, and his results could hardly be bettered His opinion was widely sought throughout Glasgow and the West of Scotland He published little, but he turned his artistic talent to account in his *Atlas of Anatomy for Nurses* published in the 30s He was also one of the first surgeons in Scotland to realise the importance of the cine camera in recording operative procedures and teaching students Many of his films were demonstrated before the Southern Medical Society, of which for a time he was president, and they will be long remembered

He was a modest, kindly man with a quiet, charming manner and a great capacity for friendship His death leaves a wide gap in the surgical ranks in Glasgow, where he was honoured and loved

Mr Burdon leaves a widow and two children.

Births, Marriages, and Deaths

BIRTHS

JAGO—On June 21 at Charing Cross Hospital London to Dr Margaret Jago wife of Douglas Hewitt a second son—Adrian

Notes and News

THE M.R C

THE Medical Research Council, like a well rooted tree, has ramified prodigiously since, in 1920, it was planted in the plot occupied since 1913 by the Medical Research Committee The luxuriant foliage on most of its branches conceals from most eyes the supple wood beneath Those who would like to see more of this may turn to a pamphlet [1] just published, which shows the structure in simple outline

REMUNERATION OF SENIOR HOSPITAL MEDICAL OFFICERS

COMMITTEE B of the Medical Whitley Council has agreed that, in accordance with an Industrial Court award,[2] the remuneration of S H M O S shall be increased by £75 a year as from April 26 this year The new scales are as follows

Main scale—£1575 × £50 to £2025
Scale for those appointed at age 30 or less—£1475 × £50 to £2025
Scale for those appointed at age 31—£1525 × £50 to £2025

ST THOMAS'S HOSPITAL THROUGH EIGHT CENTURIES

THE history of St Thomas's Hospital, London, is illustrated by an internal exhibition of archives in the grand committee room of the hospital which continues until 1 P.M this Saturday The records of the hospital begin in the 13th century and they include early maps and deeds, accounts minute-books, and photographs On show are autographed letters from Queen Elizabeth, Oliver Cromwell, and Charles II that from Oliver Cromwell recommends, in curious grammar, the appointment of "a man thoroughly tried in ye service of ye state, & found able & faithfull in his profession," but despite this testimonial the candidate was unsuccessful A salary book, 1657–77, contains the signature of Thomas Hollier, who operated on Samuel Pepys. The Treasurer's weekly accounts in 1704 include the payment of 3*s* 4*d* to Mr Ferne, one of the surgeons, for taking off a leg, and "Paid the Helper in the Kitchen as usual 3*s* 4*d* There are the orders for "cubbs" drawn up on Feb 12, 1702 (Old Style) The more official title was "covenanted servants," but students were first mentioned as "cubbs" towards the end of the 17th century (in 1699 the rule was made that they were not to keep their hats on in the wards), and the regulations of 1702 mark the formal beginning of the medical school Intending "cubbs" had to produce a testimonial that they had served a surgeon for five years and that they were of sober life and conversation One cannot imagine the side whiskered earnest young men receiving their awards in a print of an early 19th-century prize-giving, being other than sober in life and conversation But among the fine pewter tankards on display are those of the students' hall.

The clerk's diary records the first patient to die in the hospital "from the effects of chloroform"—on Oct 10, 1849 A letter from Florence Nightingale in 1875 expresses strong disapproval of a proposal that ward rounds should be made in the afternoon In pride of place, of course, is the Letters Patent of Edward VI in 1551, but most fascinating are the lesser records such as the survey of farms owned by St Thomas's in 1774, which describes one tenant as "a Sot" The exhibition has been arranged by the Archivist

NEOHIPPOCRATIC MEDICINE

THE third International Congress of Neohippocratic Medicine was held on May 20–23 at Montecatini and Florence, under the presidency of Prof C Frugoni (Rome) The object of this congress, as of the previous ones, was to study the combination of modern technical medical advances with the perennial Hippocratic principles of consideration of the whole man as a person in his internal dynamism and his special environment

The first day was devoted to a review of the constitutional factors of predisposition to cardiovascular disease, tuberculosis, and cancer

The second day was devoted to the treatment of disease by methods acting on the "whole man"—the old "Airs, waters and places" of Hippocrates Papers were read on the systemic, constitutional action of mineral waters, various physical procedures, and the psychological organisation of health resorts

The third day was devoted to the personality, duties, and social rôle of the physician The congress expressed the wish for a more general application of the Hippocratic oath at graduation and for the creation of chairs of history and philosophy of medicine, with the object of helping the synthesis of medicine and the humanistic outlook in the practice of the physician

More than four hundred physicians attended the congress British participants were Sir Horace Evans, who read a paper on the constitutional predisposition to cardiovascular disease, and Prof A P Cawadias, vice president of the congress, who reported on the developments in the science of constitutional types—biotypology

At the end of the congress a permanent International Committee of Neohippocratic Medicine was instituted Much of the success of the congress was due to the energy of the president and to the activities of the secretaries, Prof J Delore (Lyons) and Prof D Scalabrino (Montecatini)

University of Cambridge

At a congregation on June 7 the following degrees were conferred

M D—*A C Elithorn Rodney Finlayson, W D Foster *I W de D Gregory, H E Lockhart Mummery, P K Robinson C E D Taylor

M B—M H Heycock, D L Miller, Helen J Pegg

* By proxy

University of London

Dr K R Hill, professor of pathology in the University College of the West Indies, has been appointed to the chair of pathology tenable at the Royal Free Hospital School of Medicine

Professor Hill graduated B SC with first-class honours in the University of London in 1932, and qualified M R C S from Westminster Hospital in 1937 He subsequently graduated M B in 1943 and M D (pathology) in 1946 Throughout the 1939–45 war he served in the R A M C as a specialist pathologist with the rank of major He held a Rockefeller fellowship in 1947–48 He was appointed assistant pathologist to the Royal Victoria Infirmary, Newcastle upon Tyne and lecturer in pathology at King s College University of Durham Before going to the West Indies he was on the staff of the pathology department of Johns Hopkins Hospital Baltimore He is a member of the W H O Expert Consultants Panel on Treponematoses His publications include accounts of work on yaws and on liver disease in Jamaican children

The title of professor of human metabolism has been conferred on Dr C E Dent *in respect of his post at University College Hospital Medical School*

Dr Dent graduated B SC in 1931 and PH D in 1933 in the University of London He engaged in research work in organic chemistry at the Royal College of Science from 1931 to 1934 and with Imperial Chemical Industries from 1935 to 1937 In 1939–42 he undertook secret chemical war work and in 1942 he was consultant in chemistry to the War Office He qualified M B from University College Hospital in 1944, gaining the M R C P in the same year After qualifying he was house physician to Sir Thomas Lewis, and for the next two years he was assistant on the medical unit at University College Hospital Medical School In 1946–47 he held a Rockefeller travelling fellowship in the U S A Returning to his appointment in London he was elected Foulerton research fellow of the Royal Society, and in 1949 he graduated M D In 1951 he took up his present post of reader in medicine at University College Hospital Medical School He was elected F R C P in 1951 Dr Dent's many investigations have been concerned predominantly with the metabolism of calcium and of amino acids

University of Bristol

At the final examination for the degrees of M B CH B the following were successful

Pauline F Haswell D H Wright (with second class honours) Miriam M Alderwick, Babatunde Oladipo Amure Elizabeth M F Andrews J H Andrews J C Bailey F P Beck W F Benney B T A Clarke, Ruth E A Coles H F Cramp J D Davison K M Evans Irene F Gibbs P M Gill C L G Hale A F Hickson A L Horton Rachel M Hulbert A T Lloyd, Sheila M McClements June M McLeod Terence Morley R W Morris Anezionwu Nwankwo Okoro, K M Parry Weekakkodige Fredrick Perera C K Protheroe M J Rose W J Stephen S J Strong J P Telling M J Watson A H F Williams Mary B Wilson C H Wood

University of Liverpool

As a tribute to Sir Henry Cohen professor of medicine in the university, the family of the late Sir Montague Burton has given £50,000 to the appeal for £500,000 which the university launched on June 27

Ministry of Health Appointment

Dame Enid Russell Smith has been appointed deputy secretary to the Ministry of Health in succession to Sir Frederick Armer, who is to retire next November

General Medical Council

The next session of the Medical Disciplinary Committee is to begin on Tuesday, July 17 at 10 30 A M

Institute of Child Health

The Alex Simpson Smith lecture for 1956 will be given at the Hospital for Sick Children on Tuesday, July 17, at 5 P M by Dr William T Mustard, of Toronto, whose subject will be the Surgical Correction of Total Anomalous Pulmonary Venous Drainage Tickets may be had from the dean, Institute of Child Health, Hospital for Sick Children, Great Ormond Street, London, W C 1

More Mental Nurses

Mr R H Turton, the Minister of Health, speaking on June 23 to the Association of Hospital Matrons, said that in the first quarter of this year there was an *increase of 270 nurses* in the mental hospitals and 175 in the mental deficiency hospitals The most welcome feature of all in his view, said the Minister, was the increase in student nurses In mental hospitals there were 143 (10%) more male student nurses, and 109 (5%) more female student nurses In mental deficiency hospitals, *the increase in male student nurses* was 16 (6%) and of female student nurses 36 (8%) These increases had occurred before the recent salary settlement

Royal Society of Tropical Medicine and Hygiene

At this society's annual meeting on June 21, Prof R M *Gordon, the president, presented the Manson medal to the* widow of the late Brigadier J A Sinton, F R S, awarded in recognition of his outstanding work on malaria and other tropical diseases while serving in the Indian Medical Service Sir Leonard Rogers, F R S, received the Laveran gold medal of the Societé de Pathologie Exotique for his pioneer work—*also* while in the Indian Medical Service—on such fundamental studies as the treatment of amoebiasis with emetine, the treatment of leprosy with chaulmoogra derivatives, and the epidemiology and control of leishmaniasis

Mental Deficiency Laws and Administration

At a conference to be held by the National Council for Civil Liberties on Saturday, June 30, a report will be given on the council's six years' work on legal aspects of the care of mental defectives Reference will be made to cases of lengthy detention brought to an end by the council s intervention, and proposals will be put forward "to deal with the position of a large number of people whose detentions would appear to be illegal, in consequence of the High Court decision in the Kathleen Rutty case" The sessions will take place at the Beaver Hall, Garlick Hill, London, E C 4 at 2 30 P M and 6 P M, and the opening paper (What is Mental Deficiency ?) will be given by Dr Bruce Cardew

administrative medical officer of a regional hospital board, was elected president of the Northern branch of the Society of Medical Officers of Health in 1953

In national and international spheres and on central advisory committees Patterson s advice was often sought On any committee he was a tower of strength he had always read the papers and formed his own view, which he put forward clearly and persuasively, often ending with a charming smile and a diffident question as to whether he had expressed accurately his colleagues' views His contributions none the less could be outspoken, and he had no hesitation in joining the unpopular side when he thought it the right one To the North-East region—which felt itself in some danger of being overlooked—it was a great satisfaction that its chief hospital officer should enter the lists so strongly for a reasonable allocation of central funds, and not without success, as was his wont

Though to some he may have appeared a somewhat lonely figure, and others may have thought that his intense concentration on the matter in hand left little time at work for casual or "off record" conversation, Patterson had a "second personality ' reserved for his home and family life He was above all a family man, and those who were privileged to see him with his wife and children in their home saw happiness and a family unit at its best He and his wife were friends from childhood, and she has five children—a married daughter, and two older and two younger sons

He died suddenly when attending a hospital meeting in Sunderland Some of his friends had noticed that he looked tired during the last few months, but there had been no diminution in the vigour of his mind, nor had he ceased to throw himself heart and soul into any task which confronted him The personal notes which follow are taken from tributes received from associates

* * *

Dr Patterson had a strong and independent mind and was fearless in deviating from the "official" line, whether of the Ministry or of his own group, if he thought differently His approach was logical and practical, he was a shrewd judge of human beings, and he sought means that he knew from experience worked He made his contributions in debate in a quiet voice, with a smile upon his face and with a roving eye which twinkled as he saw approving glances on the other side of the table On the rare occasions on which I have heard him on the platform he held his audience by logic, fairness of mind, and force of personality

Since 1948 I have had a number of official "field days" with him in the territories of his board

He would prepare a programme of visits and of topics to discuss The visits were to sites for new hospitals, say for West Cumberland at Whitehaven or for the new town at Peterlee, or to existing hospitals where extensions were pending or where new buildings deserved study as at Carlisle or Durham or Shotley Bridge However well prepared he was, and confident that his proposal was sound, he valued the criticism or opinion of any knowledgeable person, and he prudently sought by such means as this to gain informally the official viewpoint so as to avoid delay or foundering later of the schemes he was promoting for his board The hospitals and sites were always inspected but there was never enough time for the discussion of the many subjects of policy and practice within the National Health Service on which he offered reflections and sought those of others

These days with Patterson were always a delight His interest in all aspects of his "charge" was deep and lively, his judgments on people when not generous were just and restrained, he had an optimistic and forward-looking mind, his courtesy was unexceptionable, his humour of the Scottish sort, quiet and pawky We should be thankful for the example of such a man

C T M

I had the privilege of seeing Dr. Patterson at close quarters over a sixteen-day period when we were both among the delegates sent by the United Kingdom Government to a course organised for *fonctionnaires* of the Brussels Treaty (now Western European Union) governments in France last summer

We were both members of a group that studied the organisation of hospital services we visited a number of French hospitals and enjoyed much generous French hospitality I do not think that Dr Patterson was altogether in his element under these conditions—I suspect that his good Scottish soul would have preferred something a little more austere in the eating and drinking for instance, and none of us British were at home with the language—but he rose above these difficulties splendidly, and I think the whole of our group conceived a very real affection, as well as admiration, for him before the course was over. I specially admired his dogged refusal to allow himself to be swept away by the rapid pace of the French *exposés* to which we listened, and by his frequent interventions, with forefinger uplifted and that little smile at the corner of the mouth, to clarify, in slow, simple French with a pronounced Scottish accent, some point which he felt had not been properly covered, or to explain how much better these things were ordered in the Newcastle region At the very outset of the course he made his mark, at the session when each of us was called on to introduce himself—in French "Mon nom est Patterson" he announced, "je suis écossais, mais je travaille depuis vingt ans (or was it more ?) dans le pays de mes ennemis" I should like to feel, as I am sure would the rest of the *stagiaires*, that we could all, national *ennemis* of the past and international colleagues of the present, claim his personal friendship

A R. W B

His appointment was the first act of the Newcastle Regional Hospital Board, and a most fortunate decision it proved A Scot educated in Scotland, an administrator whose professional life had been lived in the South of England, he came as a stranger to the North-East But so thorough was his method and so quick his apprehension that in a very short time he was so much at home with the region and the people in it that it was difficult to think of him as belonging anywhere else He was admirably fitted, both by temperament and training, for the responsibilities of his office He was never timid either in what he did or what he advised On the contrary, he was bold and decisive and the event has proved his wisdom Human, conscientious, and highly intelligent as he was Patterson addressed himself to his duty with something of a fervour of dedication with the result that, under his impulse, a great deal of reorganisation and expansion, particularly in the consultant services, was very rapidly achieved for a relatively small expenditure But he was always insistent that only heavy capital expenditure could bring real relief and improvement to those parts of the hospital service most in need of them, and he chafed sorely, as others have done under the severe financial restraints which prevented them Happily, he served long enough to see the fruits of his early work and the commencement of some at least of the larger projects he had proposed

Although he had made the deliberate choice, at an early stage, of a career in administration rather than in clinical medicine, the choice had clearly not been an easy one As his academic record and professional distinction showed, he had high intellectual gifts, and to visit a hospital with him was to know that he had a real compassion for the sick But he had chosen a remoter field and was resolved to make it beneficent That he succeeded there could be no doubt The inspiration of his work came from a compassionate heart and his skill in execution from an acute and cultivated mind tempered by long experience One of his gifts was a remarkable memory stored both with the kind of information for which other people have to refer to their files, but which he could mobilise at a moment's notice and with much else besides In conversation with him it soon became clear that, at one time or another he had read widely in general literature and remembered what he had read In his professional field there was none better at presenting a case with clear and cogent reasoning supported by all the relevant facts, which he had immediately at command This is not to say that he had no prejudices he would have been more than human had that been so. But, once convinced, he discarded them in a disarming way Although he knew how to delegate duties without loosing grip or authority over the field of action as a whole, he could never for long relax the pressure on himself This was the forfeit he paid for enthusiasm. To his abilities experience and knowledge he added great charm of manner These qualities of mind and heart made him not only a fine administrator, the admirable chief officer that he was, but the well-loved friend of those whose fortune it was to work with and learn from him and who have now to mourn his untimely death

E F C

Cicero in *The Offices*, referring to public officials, wrote

> “But he who takes on him a public trust, should see that he himself be qualified for the management of it, in considering which there is a double extreme to be carefully avoided, that he neither despair through mean timidity, nor yet be over confident through eagerness of desire, and lastly, in whatever he sets about, let all things be diligently and carefully put in order, before he goes on to the execution of it”

This reference to characteristics held to be desirable in a public official could not be illustrated by a finer example than the personality and work of William Patterson All things were diligently and carefully put in order before he went on to the execution of his duty As a result, his work will live for many years to come

W S W

ETHELBERT REST FLINT

M B Leeds, F R C S

Mr E R Flint, emeritus professor of surgery in the University of Leeds, died at Leeds on Jan 5, after a long illness

Born in 1880 at Scarborough, and educated there, he received his medical training in the Leeds School of Medicine and qualified in 1905 After holding a house-appointment at the Norfolk and Norwich Hospital he returned to Leeds in 1907 as house-surgeon at the General Infirmary He spent the next four years in general practice, an experience which he always regarded as of the greatest value In 1911 he was appointed resident casualty officer at the General Infirmary and in 1912 resident surgical officer The same year he took the F R C S On the outbreak of the 1914-18 war he was commissioned in the R A M C, but in fact all his service was done in the Infirmary Owing to the absence of the honorary surgeons on war service he shouldered a tremendous burden of work and in two years he did 6140 operations on civilians and wounded soldiers M J S recalls that “for weeks on end Flint was never out of the hospital (except that he slept out—on the roof of the Infirmary porch, where he had a protective awning erected) or out of surgical attire by day All or nearly all the house-surgeons of the war period were undergraduates, and the weight of responsibility which he bore would have crushed a lesser man To him, it was but a stimulant to increased effort”

Photo Press (Leeds)

The war over, he presently resigned his joint office of surgical registrar and tutor to become private assistant to Sir Berkeley Moynihan He held this post until 1926, but meanwhile, in 1922, he was elected an honorary assistant surgeon to the Infirmary, and, in 1933, full surgeon He was also consulting surgeon to the Marguerite Hepton Orthopædic Hospital, Thorp Arch, to Batley and District General Hospital, to Malton Cottage Hospital, and to the General Hospital, Halifax In 1940, after he had joined the consulting staff of the General Infirmary, he again undertook important surgical duties at the Clayton Hospital and Pinderfields Hospital, Wakefield He was also a member of the Leeds and West Riding Medico-Chirurgical Society for over forty years, an original fellow of the Association of Surgeons of Great Britain and Ireland, a fellow of the Royal Society of Medicine, and a member of the Moynihan Chirurgical Club

Flint was thus fully and usefully occupied in the clinical field, but he also did excellent work on the academic side In 1922 he had been appointed clinical lecturer in surgery in the University of Leeds and for some years he was an honorary demonstrator in physiology He also from time to time carried out research in other departments, including investigations into the ætiology of biliary-tract infections and a study of liver function in cholecystitis and cholelithiasis He investigated the abnormalities of the right hepatic, cystic, and gastro-duodenal arteries and of the bile ducts, and he published several papers with colleagues in the departments of pathology and bacteriology He was Arris and Gale lecturer in the Royal College of Surgeons in 1923 and again in 1930, and a Hunterian professor in 1933 In 1934 he was appointed to the chair of clinical surgery at Leeds, which he gave up on his appointment to the chair of surgery two years later In 1940 he was made emeritus professor

Outside his professional work Flint was a distinguished athlete, and represented his county and the North of England at hockey for many years As a good golfer he also enjoyed this game He won the Moynihan golf cup in 1914 and again in 1919, and continued to play until he was over 70

Of his work in the operating-theatre G A writes “He will always be remembered as a general surgeon of outstanding brilliance and dexterity Although most actively engaged in abdominal surgery, there was no field in which he was not proficient, possessing quite remarkable talent and instinct, always calm and unruffled, he could make up his mind quickly and act promptly He possessed a tremendous capacity for work, as evidenced by his lengthy operating-lists which he carried out so expeditiously and without any apparent fuss He was very modest, quiet, and reserved, but when he did engage in discussion he contributed something valuable and worth listening to As a colleague no-one could have been more loyal His services were continuously at the disposal of his colleagues and many have cause to be thankful to him.”

M O also writes of Flint's remarkable dexterity which “seemed to make him almost independent of an assistant, and sometimes of an anæsthetist when he used spinal anæsthesia During the 1914–18 war he had acquired an exceptional surgical experience and astounding technical ability, and his great experience, especially of abdominal surgery, enabled him to work much faster than most people For instance he performed a partial gastrectomy usually in about 40 minutes He was a kindly man, not given to saying unnecessary words, and was always rather shy of the limelight He was gentle and quiet with his patients and helpful to his assistants He will be remembered throughout Yorkshire for his kindness, his hard work and great surgical skill”

“As a medical colleague,” writes, C W V, “I treasure the memory of the quickness and dexterity with which he carried out the operation for infant pyloric stenosis—a relatively insignificant operation when put against the background of major surgery His disposition was inclined to be shy and reserved, but behind this attitude he was gentle, kindly, and friendly and one who was never hurried or ruffled under the stress of work Our feelings of sorrow, pity, and loss are the more poignant because the last years of his long and arduous life in the service of others were clouded by disability which denied him the enjoyment of a happy and restful retirement which no man could have more deserved”

In 1918, Professor Flint married Miss Alicia Bay Farrer, who survives him with three sons

JOHN PUNNETT PETERS

M D Columbia

Dr Peters, who died on Dec 29 at the age of 69, had been John Slade Ely professor of medicine at Yale University since 1927 He will be remembered, as a scientist, for his pioneer work on the application of chemical observations to clinical medicine, as a doctor, for his concern that medical care should be accessible to the whole community, and, as a citizen, for his

St George's Hospital, London

Postgraduate demonstrations in neurology and psychiatry are being held at the medical school at 5 P M on Thursdays from Jan 12 to March 15 They are open to doctors without fee

Social Medicine Research Unit

The Social Medicine Research Unit of the Medical Research Council has been transferred to the London Hospital Letters should be addressed to the unit at the London Hospital Research Laboratories, Ashfield Street, London, E 1 Tel Stepney Green 5257

Royal Northern Hospital Centenary

On June 26 the Duke of Gloucester is to preside at a dinner for past and present members of the consultant and resident staff of this hospital and their wives The dinner will be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W C 2 Those who hope to attend should write to the hon secretary, Staff Dinner, Royal Northern Hospital, Holloway Road, London, N 7, as soon as possible

British Society for Research on Ageing

On Friday, Jan 20, at 2 30 P.M, a meeting on connective tissue and its changes with age will be held at the General Infirmary, Leeds Further particulars may be had from Mr G H Bourne, D SC, hon secretary of the society, London Hospital Medical College, E 1

Runwell Hospital, Essex

The sum of £10 000 has been granted by the Peel Trust, under the ægis of the Mental Health Research Fund, to Runwell Hospital for research on the incidence of temporal lobe epilepsy in epileptic colonies and mental deficiency institutions The work is to be carried out under the direction of Dr D W Liddell with the help of a full time research fellow A new electro-encephalograph is being supplied by the Fund

Dr. G D Fraser Steele has been appointed whole time consultant psychiatrist to the hospital, Dr J H Margerison whole time research assistant in the senior registrar grade (Peel Trust), and Dr J E Boulding whole time clinical research fellow

"*Look around for some subject on which we are all agreed, and start thinking for yourself You will find you are on virgin ground*"

As far as I am concerned, when I have talked about the orthodox, I have in fact meant little more than the views I hold myself Let me apply the acid test What did I consider orthodox and heterodox twenty five years ago?

I described an operation I had invented myself for the treatment of right sided abdominal failure—right hemicolectomy, with transplantation of the ileocæcal sphincter, carrying its nerve and blood-supply, into the transverse colon I was very pleased with this operation then The fashionable London surgeon of the day approved of it, and did fifty in the next six months I have never done it again, and I have, like most surgeons, steered entirely clear of the right sided abdominal failures Those that are fortunate enough to escape the underworld of surgery who still make a living out of pexy operations, now go to the psychiatrists or to Christian Science, which is much the same thing Yet in the *Medical Annual* of 1930 I find that one surgeon reports one hundred and fifty nephropexies, and many surgeons advocate colopexy My operation was very much better

In the surgery of peptic ulceration I praised gastrojejunostomy and I criticised the Billroth-I operation Today I could not agree less Though I still love doing a gastrojejunostomy, I ceased to regard it as a rational procedure twenty years ago I doubt if I have done half a dozen since the war On the other hand, I regard the Billroth-I gastrectomy as one of the best operations in surgery when the duodenum is normal (that is, in gastric ulcer), and one of the worst operations in surgery when the duodenum is scarred (that is, when done for duodenal ulcer)

I criticised the Billroth I twenty five years ago, on the following grounds

> The pyloric end of the stomach and first part of the duodenum are poor surgical material, thick, friable, and vascular, they must be mobilised for approximation, and are pulled from their natural line and under tension after suture, they are not readily controlled by clamps When an anastomosis is made between them bleeding is troublesome at the time, leakage is not uncommon afterwards, and the finished operation is seldom a really satisfactory craftsman's job"

Those were the criticisms by a young surgeon of a technique he had not yet mastered The gastroduodenal anastomosis can be done with complete safety, and is a perfect craftsman's job if the material is good A stoma, like a sphincter, should be perfectly mobile It should be free to move with the movements of peristalsis, or with the displacement of its component parts or of its neighbours When the resection has been done for duodenal ulcer the stoma is not mobile, for the distal component is tethered by its fusion with the head of the pancreas and by the entry of the common bile duct

To one who takes the long view—and I am sorry to say that I am now able to do that—the Billroth I operation is following today the path that gastrojejunostomy followed in 1920 The operation gives such excellent results when it is done for the proper indications that it is being applied wholesale to cases for which it is entirely unsuitable The bad results are already accumulating, but they are as yet known only to the few, for no surgeon ever reports bad results, certainly not his own When they are known sufficiently widely, I fear that the Billroth-I operation may be condemned as gastrectomy is condemned in some quarters today—not because it is a bad operation, but because it is done badly

Pause and Progression

For my peroration I must once again quote my former Chichester talk

"A barge making its way up the Thames from London to Oxford does not proceed at a uniform rate At times it is moving forward, at times it remains stationary in a lock, but while it is in the lock, water is flowing in from the higher streams, till finally a new level is reached and a fresh advance is possible Thus, by alternate pause and progression, it finally mounts to the highest levels So the advance of knowledge must be wayward the locks are periods of orthodoxy, the advances, of heterodoxy"

I wish that I could be as certain today of the inevitability of advance It appears too often that a surgical advance is like a wave rather than a river, a change of form in which there is little true forward motion The wave rises from the expanse of water, it mounts, for a brief period it towers above its surroundings, then at last it collapses in a welter of foam We must watch the waves of knowledge We must try to keep on the rise and avoid the backwash

EFFECT OF CHLORPROMAZINE ON CONVULSIONS OF EXPERIMENTAL AND CLINICAL TETANUS

R E KELLY
M D *Lond*, M R C P
PHYSICIAN TO NEUROLOGICAL DEPARTMENT, ST THOMAS'S HOSPITAL, LONDON, AND CONSULTANT NEUROLOGIST, MOUNT VERNON HOSPITAL, NORTHWOOD

D R LAURENCE
M D Lond, M R C P
SENIOR LECTURER IN APPLIED PHARMACOLOGY AND THERAPEUTICS, UNIVERSITY COLLEGE AND UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, LONDON

THE treatment of tetanus convulsions is attracting much attention There are two principal methods the use of sedatives and mephenesin, and the use of neuromuscular-blocking agents with light anæsthesia The ability of anæsthetists to keep patients completely paralysed yet alive for long periods has been amply demonstrated, but treatment by paralysis, quite apart from other disadvantages, must be impracticable in any country where tetanus is common and skilled anæsthetists are few, and a simpler alternative must be sought

There is need for a drug or combination of drugs which will abolish the muscle spasm without affecting respiration or abolishing consciousness Mephenesin has some of the qualities of such a drug, but it has serious clinical disadvantages including apparent inability to control the most severe cases The readiness with which physicians have invited anæsthetists to paralyse their patients is a sufficient indication that mephenesin is thought to be inadequate or dangerous

With this need in mind, one of us examined the effect of both old and new drugs on experimental tetanus in the hope of finding a substance more effective than mephenesin So far the only drugs of any promise are chlorpromazine and promethazine, which have similar chemical constitutions

Technique

Rabbits were given an intramuscular injection of tetanus toxin into one hindleg, the dose being adjusted to cause pronounced resting tetanus in the injected leg the other being minimally affected or unaffected and so acting as a control Electromyographic records were taken from both hindlegs of the conscious animal, which was supported in a canvas sling Drugs being tested were injected intravenously and their effect on the tetanus spasm observed This technique is based on that described by Wright et al (1952)

A standard afferent stimulus, consisting in dropping a weight on to the metal frame supporting the rabbit sling, was used to give a rough measure of the completeness of abolition of the tetanus

(mg per day) being 75, 180, 220, 200, 155, 225, 285, 275, 330, 250, 215, 300, 240, 115, 50, 30 The child had a slow but uneventful convalescence

We are not here concerned with general aspects of treatment, but the following features are important

1 The child was fed by stomach tube from the first He never vomited

2 A small blood transfusion, given to correct anæmia, was followed by the transient appearance of bile pigments and salts in the urine

3 Oxygen was given by a nasal tube for cyanosis due to the spasms This was thought to do more harm than good by provoking spasms and was soon abandoned

4 An intravenous drip was kept going throughout the period of chlorpromazine administration The solutions were at first 5% dextrose and then half strength Hartmann's solution (sodium lactate compound injection *B.P*), of which about 500 ml was given each day

5 The electrolyte balance was carefully controlled (Dr E Jepson), and close attention given to oral hygiene (Mr B W Fickling)

6 Considerable intravenous thrombosis occurred and was attributed to the chlorpromazine solution (25 mg per ml) despite the fact that it was diluted ten times before being injected into the tubing of the drip near the patient 10 mg of heparin was added to each bottle of intravenous infusion

7 Large doses of tetanus antitoxin were given at the start of the illness

8 Penicillin was given to prevent respiratory complications

9 Every effort was made to deprive the patient of provocative afferent stimuli

10 Very severe abdominal distension occurred towards the end of the period of chlorpromazine administration The distension subsided At the same time an erythematous rash developed on the back and scalp It never became generalised and was attributed to excessive sweating That the drug might have played a part in these cannot be denied, but it seems unlikely

Discussion

Brooks et al (1955) investigating the mode of action of tetanus toxin, found that it caused " a large development of polysynaptic reflexes " and suggested that this might be due to " the depression of inhibitory synaptic action on the interneurones " involved in these reflexes Tetanus toxin acted by suppressing synaptic inhibition only , it did not convert inhibition into excitation

Experimental work has shown that mephenesin acts mainly by depressing the spinal-cord internuncial neurones (Berger 1947) and the brain-stem reticular formation (Henneman et al 1949) Dasgupta and Werner (1955) have shown that chlorpromazine almost certainly has similar actions

In clinical medicine mephenesin is known to be active against tetanus muscle spasm (Belfrage 1947) and against spasticity and parkinsonian tremor (Schlesinger et al 1948)

Chlorpromazine is also effective against spasticity and parkinsonian tremor (Basmajian and Szatmari 1955, Kelly and Laurence 1955) and against rabbit tetanus, as described earlier in this paper

It was therefore reasonable to suppose that chlorpromazine would be effective against tetanus in man The dose of mephenesin effective against local rabbit tetanus is 12 mg per kg body-weight, which is comparable to that known to be effective against tetanus in man (Davison et al 1949, and many other reports)

Pentobarbitone will reliably abolish rabbit tetanus only in doses which cause loss of consciousness (unpublished observations), and this finding agrees with clinical experience of barbiturates in tetanus

It therefore appeared likely that chlorpromazine, in the dosage which is effective against rabbit tetanus (1 0 mg per kg body-weight), might be useful in the treatment of human tetanus either alone or in combination with other drugs Infused carefully, 1 mg per kg body weight is not an excessive dose to give intravenously to man

In addition to the central effects of chlorpromazine Burn (1954) reported that 3 mg per kg body weight had a direct depressant effect on skeletal muscle of cats Such an effect could play a part in producing the results reported here

While these experiments were being made, Hougs and Andersen (1954) published observations on the effect of chlorpromazine and promethazine on local tetanus in anæsthetised rabbits The results recorded here substantially agree with theirs

The present case is reported, not because it is thought that the outcome of one case can provide conclusive evidence of the value of a drug but because it was a treatment chosen in the light of experimental evidence. It is our opinion that, if uncontrolled, this child would have died , but no doubt he could also have been treated successfully with thiopentone (with the concurrent disadvantage of unconsciousness), with neuromuscular blocking drugs (with the necessity for continuous anæsthesia as well as artificial respiration), or with mephenesin (which is short-acting and has the disadvantage of having to be given in very large volumes of fluid by vein to avoid the hæmolysis which strong solutions cause) Chlorpromazine was used since it offered a possibility of controlling the convulsions without any of these disadvantages

Possibly the most effective method will be to use a mixture of drugs, but it would be difficult to find two people agreed on the composition of the mixture This situation is due to the absence of information on the relative efficacy of individual drugs against tetanus convulsions , and without this information the ideal combination is unlikely to be found

To have given other drugs with the chlorpromazine would have prevented any definite conclusion as to whether the drug was capable of arresting tetanus spasm The knowledge that chlorpromazine is more effective against tetanus in rabbits than are other drugs such as mephenesin, and the belief that there is no significant difference between animal and human tetanus, justified the very large doses

We conclude that chlorpromazine is capable of controlling tetanus in man but offer no opinion on what place it may have in routine treatment If the effect reported here is confirmed in other cases this drug might then be tested in combination with other drugs of known action against tetanus—e g , barbiturates, mephenesin and promethazine

When treating severe tetanus boldness may be required in pressing drug therapy to the limits of safety If the physician is not ready to do this he is liable to find himself at critical moments either changing from one *drug to another, adding different drugs,* or resorting prematurely to neuromuscular blocking agents

Forbes and Auld (1955) report the successful use of ' constant intravenous infusion " of thiopentone, succeeded, as the patients improved, by oral paraldehyde or another barbiturate They treated fifteen patients, sometimes using a different sedative drug as the principal agent There were no deaths and it was never necessary although some cases were severe, to proceed to the use *of neuromuscular blocking agents* They aimed at the abolition of severe convulsions and opisthotonos, but not at complete flaccidity This technique, effective though it proved, must inevitably result in long periods of unconsciousness (Forbes and Auld give no information on this point), and this may account at least partly for the high rate of respiratory complications (ten patients required tracheotomy)

It is by work such as this, in which treatment was virtually *confined to* the use of barbiturates, that the efficacy of drugs against tetanus convulsions can be compared, and by such comparisons the reign of chaos over tetanus treatment may be ended

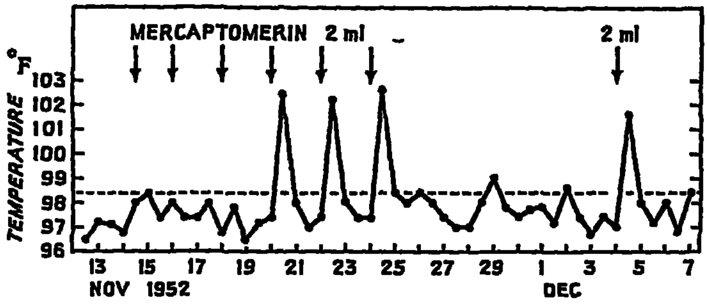

Fig 1—Pyrexia after mercaptomerin in a woman of 70 with congestive failure

one year, swelling of the ankles for one month, and attacks of nocturnal dyspnœa for three weeks She had had pernicious anæmia, treated regularly and adequately with 'Anahæmin,' for sixteen years Two months before admission her appearance and behaviour suggested myxœdema and subsequently she had thyroid (gr 2 daily) without obvious effect There was no personal or family history of allergy and she had not previously had any organic preparation of mercury

She had severe orthopnœa and cyanosis with signs of congestive failure including moderate subcutaneous œdema Pulse 100, regular Blood pressure 170/110 mm Hg Heart size uncertain because of obesity E C G showed left bundle branch block Urine normal

Treatment in hospital initially included bed rest, morphia, and digitalis folia (gr 3, reduced later to gr 2, daily) When dyspnœa and œdema were unrelieved, mercaptomerin was started (2 ml on alternate days subcutaneously) The resultant diuresis, though small, was considered worth while and the treatment was continued After the fourth injection she became febrile but without symptoms or other physical signs About one hour after each of the fifth and sixth injections she had rigors followed by about twelve hours of fever (maximum 102 4°F) (fig 1) Each was accompanied by some *increase in cyanosis, which was generalised, and by malaise* and anorexia, the sixth injection causing more subjective upset than the fifth None of these three upsets caused concern to nurses or doctors, and twenty-four hours after each of them recovery appeared complete At the time of the third reaction the white cell count was 14,800 per c mm (polymorphs 88 5%, eosinophils 0 5%, lymphocytes 10 5%, monocytes 0 5%) No malaria parasites were found on repeated examinations

At this point it was recognised that the febrile upsets were probably related to the mercurial drug Other patients in the ward who were receiving the same batch of drug did not react in this way, and the readily available literature on mercaptomerin gave no reference to febrile reactions

On *Dec 4* the seventh dose of 2 ml was given subcutaneously This was followed after one hour by rigor, extreme malaise, and cyanosis (temperature 100 6°F, pulse 126, regular, small volume, and at times impalpable, blood-pressure 90/60) Later that day she vomited twice and passed six fluid stools

On *Dec 5* she was afebrile but still drowsy and cyanosed with evidence of peripheral circulatory failure (blood pressure 60/35) Adrenaline by injection appeared to increase the cyanosis Blood chemistry Na 310, Cl 342, K 21 5 mg per 100 ml No more than 1–2 oz of urine was passed, incontinently During the day she had oral cortisone (150 mg in three divided doses) and was kept in an oxygen tent She received no other corticoid The drowsiness and signs of peripheral circulatory failure lessened during the day, the pulse volume improved, and the blood pressure rose to 90/60 The 24 hour output of urine was 18 oz

On *Dec 6* the slow improvement was maintained Blood-pressure 100/70 Urine output 12 oz E C G no change since admission

She continued to improve slowly though blood-pressure remained low and on Dec 19 was only 150/85 At no time during the stay in hospital was any preparation of liver, vitamin B_{12}, or thyroid given to her

Case 2 —Mr H H, aged 57, was admitted to hospital on Oct 17, 1953, with a nine month history of dyspnœa on effort and more recently attacks of paroxysmal dyspnœa His own doctor had already given several injections of mersalyl without untoward effect There was no personal or family history of allergy

He had an enlarged heart with atherosclerotic aortic stenosis and auricular fibrillation Blood pressure 150/90 E C G showed left ventricular preponderance Urine normal

In hospital he was confined to bed and digitalised On Oct 18 1 ml of 'Neptal' was given intramuscularly without ill effect On Oct 20 he received mercaptomerin (2 ml subcutaneously) and this was repeated on alternate days until he had received 10 ml of the drug in five doses About twenty four hours after the first injection of mercaptomerin a generalised irritating erythematous rash developed This was not associated with fever and rapidly receded under treatment with promethazine ('Phenergan') (25 mg b d) It was thought that the rash probably indicated sensitivity to a barbiturate used to sedate him, but to determine the offending preparation *particular drugs were discontinued and then reintroduced* Butobarbitone ('Soneryl') (gr 3) caused no untoward reaction

On Nov 11 a test dose of 0 5 ml of mercaptomerin was injected subcutaneously Within a few minutes erythema developed around the injection site About an hour later the patient experienced tightness in the chest and epigastrium and breathing became laboured He rapidly became extremely shocked (pulse 45, blood pressure 70/30, heart sounds so soft as to be barely audible) He remained in this state for about an hour and then slowly improved so that within six hours he was relatively well again His condition was so suggestive of an acute coronary attack that two E C G s were taken The first, twenty minutes after the onset of the attack, showed increased T wave inversion in the left lateral chest leads A further tracing next day was substantially the same as that on admission and showed no evidence of myocardial infarction His further stay in hospital was uneventful There was no rise of temperature after any of the injections of diuretic

Case 3 —Mr B H M, aged 47, was admitted to hospital on Sept 27, 1954, with increasing dyspnœa on exertion and angina of effort for one year Ankle swelling had been noticed more recently There was no personal or family history of allergy

There were signs of congestive failure and the heart was moderately enlarged Pulse irregular due to auricular fibrillation Blood pressure 120/60 The lungs showed signs of emphysema and congestion

Measures to relieve heart failure included salt restriction, *digoxin, and mercaptomerin, which was given subcutaneously* in a freshly prepared solution Three injections, each of 2 ml, were given in all and after each the diuresis was satisfactory Thirty six hours after each dose the temperature rose (fig 2) and the febrile response increased with each injection The first two reactions were small and there were no other symptoms, but the third was accompanied by malaise and chills Mercaptomerin was therefore discontinued, and during his remaining stay in hospital he was afebrile Serum chemistry and urine were normal throughout No other cause for febrile episodes was discovered

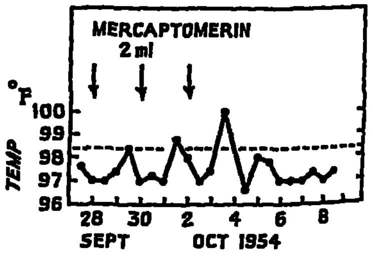

Fig 2—Pyrexia after mercaptomerin in a man of 47 with congestive failure

Case 4 —Mr S V B, aged 47, was admitted to hospital on *Dec 7, 1953, with a three week history of angina of effort,* dyspnœa on exertion, and increasing ankle swelling There was no previous history of allergy

He had early congestive failure with distended neck veins, orthopnœa, ankle œdema, and hepatomegaly The heart was moderately enlarged Pulse regular Blood pressure 105/65 Blood count and urine were normal Chest radiograph showed lungs much striated, as in bronchitis, with a small amount of pleural elevation at the left base

Treatment included salt restriction and mercaptomerin The solution was freshly prepared and given subcutaneously Five doses were given altogether at intervals of two days, the first was 0 5 ml and the other four 2 ml each After the third injection the temperature rose, and this fever persisted for five weeks, the highest reading was 102°F On the day
